# THE EFFECTS OF CREDITOR RIGHTS AND BANK INFORMATION SHARING ON BORROWER BEHAVIOR: THEORY AND EVIDENCE

## Abstract

This paper provides a comprehensive theoretical and empirical analysis of "creditor rights" and "information sharing" throughout over 1.8 million public and private firms in Europe. We show that many of the outcomes associated with greater levels of creditor rights can be obtained with higher information sharing between banks. Both theory and empirics show that creditor rights and information sharing are associated with greater firm leverage, lower profitability, as well as greater distance to default. Moreover, both theory and empirics find that creditor rights and information sharing are robust substitutes. Our analysis suggests that poor creditor rights, which tend to be sticky over time, can be substituted by improved information sharing.

# 1 Introduction

Creditor rights impact the contracts between borrowers and lenders. When creditors believe that they are more likely to be able to recover losses, they are more inclined to extend credit. This makes it easier for borrowers to obtain capital to finance projects, ultimately leading to economic growth. The seminal work on creditor rights is La Porta, Lopez-de Silanes, Shleifer, and Vishny (1998, hereafter LLSV). LLSV show that creditor rights are functions of a country’s legal origin, determined when the country was originally colonized. Djankov, McLiesh, and Shleifer (2007, hereafter DMS) expand the analysis to show that creditor rights are remarkably stable over time, contrary to the idea that legal rules are converging to some optimal level. The two papers suggest that creditor rights are representative of the historic laws associated with each country, are relatively stable over time, and do not quickly change based on economic development, financial market development, or technological advances. As described in Acharya, Amihud, and Litov (2011, hereafter AAL), creditor rights are largely “predetermined.”

If the literature suggests that enhanced creditor rights are associated with positive outcomes, such as larger propensity for banks to lend and greater economic growth, are countries without creditor rights at a natural disadvantage? If creditor protection laws are sticky and unchanging over time, is there a way for countries with low creditor protection to realize some of the positive outcomes associated with high levels of creditor protection without changing their own creditor rights laws? This paper shows that by increasing information sharing between banks, many of the positive outcomes associated with stronger creditor rights can be realized in low creditor rights environments.

In contrast to creditor rights, information sharing has largely been increasing over time. At the country-level, more private registries and public bureaus are being established. Additionally, private registries and public bureaus have been collecting more comprehensive information about their borrowers, making lenders even more aware of borrower profiles.

Our paper makes two points. First, both creditor rights and information sharing are especially relevant for smaller, private firms. These firms may not have access to wholesale funding markets and may be more credit constrained. As a consequence, we use data that concentrates on private firms. Accordingly, the model assumes that firms can only obtain loan financing through banks. It generates a number of predictions, which are all confirmed by our data and robust to a number of additional tests. Furthermore, we bring together a number of other seemingly paradoxical empirical studies. By examining a comprehensive set of 1.8 million public and private firms in Europe with heterogeneous characteristics, we are

able to provide a more comprehensive understanding of the way creditor rights and information sharing affect borrower behavior outside of bankruptcy states. Specifically, we focus on the group of borrowers that are most likely to be reliant on bank loans and affected by the local creditor rights environment.

Second, we show that both theoretically and empirically, the effects of creditor rights and information sharing cannot be treated separately. Information sharing improves the knowledge that banks have on the loan in their portfolio, and it will lead to better lending decisions. Fewer bad loans will end up in the banks' portfolios. However, creditor rights are relevant mostly for loans that end up in default. Hence, if highly developed information sharing is already in place, creditor rights matter less. The two are substitutes. Our model predicts that the effects of creditor rights and information sharing go into the same direction, yet one mitigates the other. The data is perfectly in line. The coefficients of creditor rights and information sharing on leverage are both positive, those on profitability are both negative, and those on distance to default are both positive. The interacted effects always have the opposite sign, just as the model predicts.

The model indicates that increased levels of both creditor rights and information sharing affect the intensity at which banks screen, which directly reduces the rate that borrowers are charged. Consequently, borrowers take on larger loans, realize lower profitability, and decreased their distance to default. They are also importantly interactive, and this substitution effect is both statistically and economically significant.

The literature on relationship banking suggests that local firms tend to acquire capital through local banks. We construct a model around an entrepreneur with a project who is attempting to obtain a loan from a local bank. In order to test the predictions within our model, we focus on private firms and subsets of firms that are most likely to be borrowing from local banks, placing both the firm and bank in the same creditor rights environment.

## 1.1 Model Description

We construct a model with two banks, each competing for borrowers in a market with search. There are two types of borrowers. Good borrower can pay back their loans, while bad borrowers will default. By exerting effort, banks can identify the bad borrowers. Competition is modeled in the style of Broecker (1990) emerges, but due to the time structure, we get rid of the mixed strategy pricing equilibria. Entrepreneurs go to one bank to apply for a loan. Depending on the loan rate, they decide what size loan they would like to apply. The bank then decides how thoroughly to screen the entrepreneur. If the screening result is

positive, the bank offers the loan. But if rejected, the entrepreneur moves on to the other bank. That bank does not know whether the entrepreneur has been rejected before, so the entrepreneur is screened again. Because the bank's screening technology is not perfectly correlated, it is possible that the entrepreneur is now granted a loan. Inherently, there is a strategic complementarity between the screening choices of the banks. If one bank screens more, it leaves more lemons for the other bank. As a result, the second bank will also want to screen more, again reinforcing the screening effort of the first bank.

We want to know how the model equilibrium depends on *creditor rights*. We assume that if a loan defaults, the bank can still get a liquidation value, which positively depends on creditor rights. In the model, if creditor rights are stronger, banks lose less money on each loan, leaving them less desire to screen. Consequently, the banks want to attract higher loan volumes, which are more desirable. In order to attract these loans, they can entice borrowers by lowering loan rates. In response to these lower loan rates, entrepreneurs then take out larger loans, which leads to increases in firm *leverage*. Due to decreasing returns to scale, the larger investment size leads to a reduced *return on assets*.

The effect of increased creditor rights on firm risk is less clear. There are two channels. The loss given default decreases, but the banks also screen less, leading to an ambiguous aggregate effect. First, because banks screen less, firm risk should increase, since more risky entrepreneurs are being granted loans. In numerical simulations, the direct effect (lower loss given default) dominates, and stronger creditor rights lead to reduced risk.<sup>1</sup> All else equal, banks would choose to lend to less risky firms, reinforcing the result in the numerical simulations. This is also consistent with the empirical results presented in the paper. However, firms may also adjust the risk choices of their projects. As creditor rights increase, the firms will avoid default by reducing risk, which is what leads to the ambiguity in the model regarding the direct effect creditor rights have on firm risk.

Next, we also model *information sharing*. The only information that is interesting for the other bank is whether an entrepreneur has previously been rejected. We model information sharing as the probability with which the fact that an entrepreneur has been rejected leaks out or is reported over by a credit registry. The predictions are very similar to those focusing on creditor rights. First, there are fewer lemons in the pool of applicants, hence banks choose to screen less and charge lower loan rates. Firms borrow more, and leverage increases. Second, the average quality of a loan increases. As a result, banks want to increase the loan volume, which they do by lowering the loan rates. Entrepreneurs take larger loans, which leads to higher leverage. Second, because of increasing investment size and decreasing returns to

---

<sup>1</sup>On the other hand, in our model, borrowers cannot choose risk like in Boyd and De Nicolò (2005).

scale, the return on assets decreases. Third, there is an ambiguous effect on risk. Information sharing reduces the risk in the pool of borrowers directly. Indirectly, banks screen less. In our simulations, the direct effect of the loss given default dominates.

Finally, creditor rights and information sharing interact in a natural way. Information sharing reduces the fraction of bad loans in the banks' loan portfolio. Because increased creditor rights apply only to bad loans, the incremental effect of creditor rights is reduced if information sharing is already strong. In other words, creditor rights and information sharing are substitutes: for leverage, profitability (ROA) and risk.

## 1.2 Empirical Results Preview

Our empirical analysis examines 1.8 public and private firms in Europe from 2006-2014, utilizing the Amadeus database. This database provides the ideal setting to test the predictions within the theoretical model due to the heterogeneity within the sample. As previously discussed, the model focuses on entrepreneurs approaching banks in order to acquire loans. The relationship banking literature suggests that small firms tend to borrow from local banks, making both firm and bank exposed to the same creditor rights and information sharing environment. Thus, the model is most directly applicable to firms that are small and private, the majority of firms contained within Amadeus.

We first examine the effect of creditor rights and information sharing separately on firm leverage. When the variables are examined separately or in conjunction with one another, we find that they have a positive effect on leverage. However, the economic magnitudes of these effects are unrealistically large, suggesting there could be an omitted variable. After accounting for their substitution effect, the impact of creditor rights on firm leverage drops 45%, while the impact of information drops by 80%, though the coefficients are still positive.

In subsequent analysis, we find that creditor rights and information both have a negative effect on firm profit and positive effects on firm distance to default. The interaction effect is always in the opposite direction, and the drop in economic magnitude persists in subsequent analysis. This result is robust to a removing firms that are less likely to be reliant on bank loans, alternative measures of both creditor rights and information sharing, controlling for law enforcement, removing country-specific industries, as well as alternative definitions of the outcome variables

Within the finance literature, both theoretical and empirical papers have primarily focused on either one mechanism or the other (with the exception of Houston, Lin, Lin, and Ma,

2010, and Brown, Jappelli, and Pagano, 2009), creating two distinct bodies of literature. Given that information sharing is increasing over time, while creditor rights remain stable at their predestined levels, we examine whether the evolution of information sharing essentially counteracts or complements some of the effects of creditor rights. The natural question to ask is if these two financial markets mechanisms meaningfully interact and how this applies to these two strands of literature.

## 2 Literature Review

**Creditor Rights Literature Review.** A large body of theoretical literature examines the supply side of the credit market and provides a framework indicating that lenders are more likely to extend credit when they have the ability to force repayment, seize collateral, or even remove management Townsend (1979); Aghion and Bolton (1992); Hart and Moore (1994, 1998). In order to test these predictions empirically, LLSV constructed the original creditor rights index dataset<sup>2</sup>, which was then expanded to a panel covering 129 countries from 1978-2004 by DMS 2007.<sup>3</sup>

Since then, the creditor rights index has been empirically examined by a number of scholars. Within the literature, it has been shown that at the country-level, enhanced creditor rights are associated with a greater ratio of private credit to gross domestic product, indicating that there is more credit in economies with greater creditor protection. Using individual bank-level data, Houston, Lin, Lin, and Ma (2010, hereafter HLLM), show that increased creditor rights lead to greater bank risk-taking, which could suggest that banks are lending to a wider pool of borrowers. It has also been shown that debt is cheaper (Qian and Strahan, 2007; Bae and Goyal, 2009). However, AAL and Acharya, Sundaram, and John (2011) show that public firm leverage decreases when creditor rights are higher, suggesting that public firms are actually borrowing less because they fear being inefficiently liquidated by creditors.

It may seem paradoxical that increased creditor rights are associated with more private credit in an economy, increased bank risk-taking, and cheaper debt, yet have also been associated with decreased borrowing at the firm-level. The natural question to ask is where is the additional credit going? Our model and empirical findings fill in this missing link by showing that small or private firms, the ones most likely borrowing from local banks, are

---

<sup>2</sup>The index components consist of restrictions on reorganization, no automatic stay of assets, secured creditor paid first, and management removal. Higher values of the index as well as the individual components indicate that creditors have more power.

<sup>3</sup>DMS utilize the same four creditor rights index components, though the values differ slightly.

able to borrow more when creditor rights are stronger, while our empirical findings confirm this prediction.

This paper extends our empirical analysis beyond the firm's decision to borrow and examines subsequent firm risk-taking and profitability, which to our knowledge, have not been analyzed for private firms. Nini, Smith, and Sufi (2009, 2012) show that creditor rights can play an active role in the governance of corporations even outside default. In a sample of public firms, AAL show that increased creditor rights lead to firms engaging in more diversifying acquisitions, causing them to decrease their overall firm-risk. Their paper shows that public firms will even compromise profitability in order to decrease their overall risk out of fear of inefficient liquidation. Consistent with AAL, our model and empirical findings show that increased creditor rights are associated with decreased profit and firm risk.

**Information Sharing Literature Review.** The theoretical literature has shown that information sharing is an important determinant of credit availability by encouraging borrowers to exert more effort into projects (Padilla and Pagano, 1997; Vercammen, 1995) and pay back loans (Klein, 1992). The empirical literature has shown that the organization structure of information sharing as well as the type of information shared is relevant. At the country level, DMS show that greater information sharing is associated with a greater ratio of private credit to GDP. Brown, Jappelli, and Pagano (2009) show that at the firm-level, information sharing leads to greater leverage, while Jappelli and Pagano (2002) show that banks lend more when there is more information sharing and take on more risk. Laeven, Levine, and Michalopoulos (2015) find that information sharing contributes importantly to real economic growth if information bureaus are privately organized and operated. HLLM find evidence that information sharing decreases bank risk-taking, since banks have a greater understanding of their borrowers.

It is important to note that to our knowledge, there are only two papers that examine a possible interaction effect between creditor rights and information sharing. HLLM show that creditor rights increase bank risk-taking, while information sharing decreases it. However, the interaction between creditor rights and information sharing offsets some of the increase in risk-taking that come from the direct effect of creditor rights. Brown, Jappelli, and Pagano (2009) find that creditor rights lead to greater firm leverage, and that information sharing only meaningfully impacts firm leverage in low creditor rights economies. Our model and findings go into the same direction. The lower creditor rights in an economy, the more relevant is information sharing. All the more, the interaction term is economically highly significant. Dropping the interaction empirically leads to unrealistically strong effects of creditor rights and information sharing.

### 3 The Model

In this section, we develop a model that predicts the reaction of firm leverage, firm profitability and firm risk on our two main determinants, creditor rights and information sharing. For convenience, we summarize our findings in Table 1.

	Creditor rights $\lambda$	Information sharing $s$	Interaction $\lambda \times s$
Leverage	+ (see Prop. 1)	+ (see Prop. 1)	- (see Prop. 1)
ROA	- (see Prop. 2)	- (see Prop. 2)	+ (see Prop. 2)
Firm risk	- (simulation)	- (simulation)	+ (simulation)

Table 1: Summary of Comparative Statics

Consider an economy with one period and two dates, 0 and 1, and three types of agents: entrepreneurs, (two) banks, and investors. Entrepreneurs have access to real investment projects but no funds. Investors are endowed with funds but do not have direct access to projects. Banks are endowed with neither funds nor projects but have access to a screening technology that they can use to evaluate projects. Hence, in the financial system, investors need to use banks as intermediaries in order to lend to entrepreneurs.

**Entrepreneurs.** There is a continuum of entrepreneurs of mass 2, each endowed with wealth  $A > 0$ . Each entrepreneur has access to an investment project. There are two types of entrepreneurs, good (fraction  $\gamma$ ) and bad (fraction  $1 - \gamma$ ). The projects of good entrepreneurs return some  $Y(I)$  per unit of investment  $I$ . Assume that  $Y'(I) < 0$  (decreasing returns to scale) and  $Y''(I) < 0$ , and additionally  $Y'''(I) < 0$  for technical reasons. The projects of bad entrepreneurs return a fixed  $y < 1$  per unit of investment. Entrepreneurs are risk neutral and protected by limited liability. They want to consume only at the later date 2. Furthermore, they bear a (small) non-monetary cost of  $c$  to apply for a loan at a bank. For exposition, assume that entrepreneurs do know their own type.<sup>4</sup>

**Investors.** There is a continuum of investors of mass  $\geq 2$ , each holding an initial endowment of  $w \geq 1$ . Investors have a utility function  $u(c_1, c_2) = c_1 + c_2/(1 + r)$ , indicating that

---

<sup>4</sup>Otherwise, why should a bad entrepreneur apply for a loan in the first place, if he knows he will fail with certainty. For the purpose of the model, we could assume that the entrepreneur has some information about his later performance, but that this information is noisy enough that also bad entrepreneurs apply for loans. Alternatively, we could assume that the entrepreneur has rather precise information about his future performance, but bad entrepreneurs receive a private benefit from carrying out the project. For simplicity, we assume that entrepreneurs have no information.

they are willing to invest their money into the bank if the expected return is at least  $r$ . Investors are passive in the model and only provide the funding.

**Banks.** There are two banks. On the liability side, each bank has access to investor deposits at rate  $r \geq 1$  (including the repayment of the principal).

On the asset side, banks grant loans. If an entrepreneur applies for a loan, the bank announces a loan rate, and the applicant chooses a loan volume. Based on this information, the bank can screen the applicant. Spending a screening cost of  $C(q)$ , a *bad* applicant is screened out with probability  $q$ . Assume that  $C(q)$  is twice continuously differentiable, with  $C'(q) > 0$ ,  $C''(q) > 0$ ,  $C'(0)$  small enough, and  $C'(1)$  large enough to guarantee an interior solution. For example,  $C'(0) = 0$  and  $C'(1) = \infty$ . Also, assume that screening costs are proportional to the loan size. The rationale behind this assumption is that larger projects are more complex and thus more difficult and costly to screen.

Screening results are uncorrelated. Good applicants are never screened out. After screening, the bank can offer a loan to the entrepreneur at the pre-specified loan rate. Entrepreneurs then choose whether to take the loan. They can also turn down the loan, and then subsequently apply for another loan at the competitor bank.

Note that banks can never tell for sure whether a loan in its portfolio is good or bad. Hence, a bank knows that some of its loans are good (they will repay at  $t = 1$ ) and some are bad (they will default). However, from an *ex ante* perspective, the loans are simply risky. The more the bank screens, the less risky they become.

**Creditor Rights.** The *bad* entrepreneurs who have not been rejected will invest at date 1. The investment project returns  $yI$ , which is never sufficient to repay the debt, so bad entrepreneurs default with certainty. The liquidation value is  $yI$ . We assume that bankruptcy law determines how this liquidation value is distributed between the lender-bank and the borrower-entrepreneur. Assume that the bank can claim  $\lambda I \leq yI$ , indicating that the entrepreneur keeps the remaining  $(y - \lambda)I$ , which is non-pledgeable for legal reasons. Since the entrepreneur can keep a positive amount, he carries out the project with negative NPV in the first place. Bankruptcy costs are largely shifted to the bank.

Also, since  $\lambda \leq y < 1 \leq r$ , the net profit  $\lambda - r$  per unit of investment will always be negative for the bank. Hence,  $\lambda$  measures the strength of *creditor rights*. The variable  $\lambda$  is exogenous to the model, so we can use it for comparative statics. If it were not,  $\lambda$  could be used by banks for screening or by entrepreneurs to signal their type.  $\lambda$  should thus be interpreted as a parameter for the legal environment, not for a specific contract.

**Information Sharing.** Banks share information about rejected entrepreneurs. Let  $s \in [0; 1]$  be the probability that a bank informs its competitor when an entrepreneur has been rejected.<sup>5</sup> For  $s = 1$ , banks fully share information about applicants, such as entering the rejection into a credit registry. For  $s = 0$ , banks do not let out any information. Also,  $s$  is exogenous to the model. Banks must report the correct information (rejection) with probability  $s$ , and they do not report anything with probability  $1 - s$ .<sup>6</sup>

**Time Structure.** The time and information structure of the game are illustrated in Figure 1. Importantly, banks do not know whether they are the first or second bank to screen the applicant.<sup>7</sup>

- Date 0 Creditor rights  $\lambda$  and information sharing  $s$  are fixed exogenously.  
Nature draws the type of entrepreneurs.
- Date 1 Each entrepreneur applies for a loan at one of the two banks.  
That bank announces a loan rate.  
The entrepreneur announces a desired loan size.  
That bank decides on its screening intensity.  
Upon a positive screening signal, the bank offers the entrepreneur a loan. After a negative signal, the bank rejects the entrepreneur, reports this with probability  $s$  to the other bank. The entrepreneur then applies at the other bank.  
Entrepreneurs with a loan offer choose the investment volume  $I$  of their projects. Investment.
- Date 2 If the project is good, it returns  $Y(I)I$ , of which the entrepreneur passes on  $R$  to the bank. If the project is bad, the project returns  $yI$ , of which the entrepreneur passes on  $\lambda I$  to the bank.

Figure 1: Time and Information Structure

---

<sup>5</sup>Bennardo, Pagano, and Piccolo (2015) model information sharing as lenders informing other potential lenders that the entrepreneur already has a loan, to prevent overlending. This problem is assumed away in our model: the complete amount  $I - A$  stems from the same bank.

<sup>6</sup>Alternatively, one could assume that banks report garbled information, with  $s$  measuring the quality of the signal. Another alternative is to interpret  $s$  as the probability that negative information just leaks out.

<sup>7</sup>Our modeling choice is closely related to Broecker (1990). However, in Broecker's paper, banks first simultaneously choose how much information to gather, and then set loan rates. The unique equilibrium exhibits a mixed pricing strategy by banks. In our model, entrepreneurs successively apply at banks. Our resulting equilibrium is in pure strategies.

## 4 Equilibrium

The model is solved by backward induction. For a given loan rate, good entrepreneurs will choose the loan size that suits them most. Bad entrepreneurs will have to pick the same loan size in order to not reveal themselves as bad types. A good entrepreneur's profit is

$$\Pi_G = IY(I) - R(I - A). \quad (1)$$

The first part in the maximum is the revenue net of repayment of principal and interest for an investment size of  $I \geq A$ . The loan size is then  $I - A \geq 0$ . The first order condition is

$$\frac{\partial \Pi_G}{\partial I} = Y(I) + IY'(I) - R = 0. \quad (2)$$

This yields the optimal  $I^*$ . Some algebra shows that the loan demand is decreasing (of course) and concave in the loan rate.

**Lemma 1**  $I'(R) < 0$  and  $I''(R) < 0$ .

If an entrepreneur gets an offer from a bank, in equilibrium, he does not turn it down. The reason is that in equilibrium, both banks offer the same loan rates. By turning down a loan, an entrepreneur would double his application costs without realizing any additional benefit.

Now, let's examine the the bank's behavior. Without loss of generality, focus on the first of the two banks. In a symmetric equilibrium, half of the entrepreneurs (with volume 1) apply first at bank 1, and the other half applies first at bank 2. First, focus on bank 2. Bank 2 accepts all good applicants (fraction  $\gamma$ ) and those bad applicants (fraction  $1 - \gamma$ ) that it has not screened out (fraction  $1 - q_2$ ). Bank 2 screens out a fraction  $q_2$  and reports those firms to bank 1 with probability  $s$  (or a fraction  $s$ ). Hence, the aggregate number of loan applicants at bank 1 is

$$1 + (1 - \gamma) q_2 (1 - s). \quad (3)$$

If bank 1 screens these applicants with intensity  $q_1$ , and  $C(q_1)$  is proportional to the loan size  $I - A$ ,  $C(q_1) = (I - A) c(q_1)$  per loan. The aggregate screening costs are

$$(1 + (1 - \gamma) q_2 (1 - s)) (I - A) c(q_1). \quad (4)$$

The number of entrepreneurs with bad projects is  $(1 - \gamma) + (1 - \gamma) q_2 (1 - s)$ . The return of these projects is  $\lambda$ , and the financing cost is  $r$ . The number of good entrepreneurs is  $\gamma$  with

a return of  $R_1$ . In sum, bank 1's profit function is

$$\begin{aligned} \Pi_1 = & (\gamma(R_1 - r) + (1 - q_1) [(1 - \gamma) + (1 - \gamma) q_2 (1 - s)] (\lambda - r)) (I - A) \\ & - (1 + (1 - \gamma) q_2 (1 - s)) (I - A) c(q_1). \end{aligned} \quad (5)$$

From this profit function, we can derive the first order conditions for the banks' decision variables. There are four endogenous variables. The screening intensity  $q_1$  and the loan rate  $R_1$  corresponding to bank 1 are endogenous, as are  $q_2$  and  $R_2$  symmetrically for bank 2. In symmetric equilibrium,  $q_1 = q_2 = q$  and  $R_1 = R_2 = R$ . Thus, only two endogenous variables remain, determined by two first order conditions. We will now see that the first order condition with respect to  $q$  determines the optimal  $q^*$  but does not depend on the equilibrium loan rate  $R^*$ . The reason for this is due to the assumption that the screening technology sorts out bad firms. Furthermore, bad firms fail and never pay interest. On the other hand, the choice of the loan rate  $R^*$  depends on the screening intensity  $q^*$ , as we will see below. Using the first order condition with respect to  $q_1$ , and taking into account that the two banks are symmetric ( $q_1 = q_2 = q$ ), we arrive at

$$-[(1 - \gamma) + (1 - \gamma) q (1 - s)] (\lambda - r) - (1 + (1 - \gamma) q (1 - s)) c'(q) = 0. \quad (6)$$

We obtain the first order condition for  $q^*$ ,

$$c'(q^*) = \frac{1 + q^* (1 - s) (1 - \gamma) - \gamma}{1 + q^* (1 - s) (1 - \gamma)} (r - \lambda). \quad (7)$$

This condition defines  $q^*$  implicitly. In order to solve for  $q^*$ , we would have to specify  $c(q)$ , restricting the generality of the model. Now, turn to the loan rate. Concerning  $R_1$ , we obtain a first order condition  $\partial \Pi_1 / \partial R_1 = 0$ . Again, in a symmetric equilibrium,  $q_1 = q_2 = q^*$  and  $R_1 = R_2 = R^*$ . Some algebra shows that  $R^*$  is implicitly defined by

$$\begin{aligned} \gamma (I(R^*) - A) + \gamma (R^* - r) I'(R^*) - (1 - q^*) (1 + q^* (1 - s)) (1 - \gamma) (r - \lambda) I'(R^*) \\ - (1 + q^* (1 - s) (1 - \gamma)) c(q^*) I'(R^*) = 0. \end{aligned} \quad (8)$$

Summing up, the symmetric equilibrium is defined by two implicit equations. (7) does not contain  $R^*$ , so it implicitly defines  $q^*$ . That solution enters into (8), which then implicitly defines  $R^*$ .

**Comparative Statics.** We first analyze how our main endogenous variables, the screening intensity  $q^*$  and the loan rate  $R^*$ , depend on the exogenous parameters, prominently creditor rights  $\lambda$  and information sharing  $s$ . We then go on and compute comparative statics for

measurable statistics such as leverage, return on assets, and aggregate risk. These can be tested in the next section.

**Lemma 2**  $\frac{dq^*}{d\lambda} < 0$  and  $\frac{dq^*}{ds} < 0$ . If creditor rights are not too weak,  $\frac{d^2q^*}{d\lambda ds} > 0$ .

All three parts are intuitive. Stronger creditor rights cut the potential loss given default for the bank, so it needs to be less reluctant when screening the loans. In addition, there is a multiplicative effect due to the strategic complementarity of banks' screening decisions. If one bank screens less, the other bank gets fewer lemons, further incentivizing the bank to screen less.

Also, the higher the degree of information sharing, the lower the bank's incentive to screen an applicant itself. This is reinforced by the strategic complementarity. If one bank has less of an incentive to screen, this further reduces the other bank's incentives and vice versa.

The cross derivative is positive. Together with the negative direct derivatives, this means that the effects of creditor rights  $\lambda$  and information sharing  $s$  on the screening intensity  $q$  are substitutes. The more you already have of one of the two, the weaker the effect of the other becomes. Note that we need the qualification that creditor rights are not too weak. Actually, the cross derivative is positive in *all* our numerical simulations. Unfortunately, the proof becomes very messy for the general case. Concerning the equilibrium loan rate  $R^*$ , we can show

**Lemma 3**  $\frac{dR^*}{d\lambda} < 0$  and  $\frac{dR^*}{ds} < 0$ . If creditor rights are not too weak,  $\frac{d^2R^*}{d\lambda ds} > 0$ .

Again, all three parts are intuitive. Stronger creditor rights lead to smaller bank losses from bad borrowers. Because of the competition, banks need to lower their loan rates. This effect is reinforced by the endogenous screening decision of banks. Second, more information sharing leads to fewer bad loans in the banks' loan portfolio. Because of competition, they must lower their loan rates. Third, if there is information sharing, there are fewer bad loans in the banks' portfolio, so the effect of stronger creditor rights is weaker.

**Predictions.** We start with analyzing how firms adjust their optimal level of leverage. If creditor rights are stronger, a bank loses less on bad loans, per unit of investment. The bank prefers to attract a larger-size loan, which implies that the loan rate must drop. Hence, we also get  $dI/d\lambda > 0$ . Furthermore, leverage is defined as debt volume over equity volume,

which in the model is simply  $(I - A)/A$ . Consequently, stronger creditor rights make leverage increase.

If there is more information sharing, fewer loans are contained within the bank's portfolio. Therefore, the bank wants to grant larger loans, which implies it needs to lower the loan rate. With the same argument as above, more information sharing also leads to an increase in leverage. The following proposition, confirmed numerically by Figure 2, is thus an immediate consequence of Lemma 3.

**Proposition 1** *With  $Lev := (I - A)/A$ , we have  $\frac{dLev}{d\lambda} > 0$  and  $\frac{dLev}{ds} > 0$ . If creditor rights are not too weak,  $\frac{d^2 Lev}{d\lambda ds} < 0$ .*

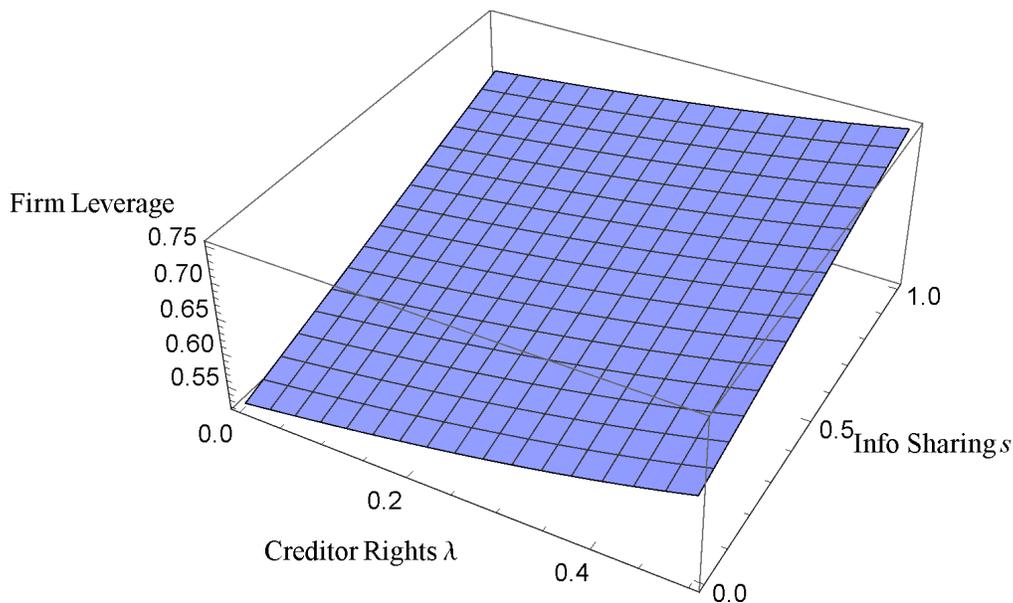

Figure 2: Firm Leverage  $(I - A)/A$

Next, consider the firms' profitability (ROA), simply defined by  $Y(I)$ , the return per unit of investment. The argumentation is parallel to the one above. If creditor rights improve, the loan rate drops. Consequently, firms demand a higher loan volume. However, a decreasing profitability of the investment project is the counterforce in the firm's decision problem. Hence, in equilibrium, projects become loss profitable (per unit of investment). The argument for information sharing is similar. The following proposition, confirmed numerically by Figure 3, is thus another immediate consequence of Lemma 3.

**Proposition 2** *With  $ROA = Y(I)$ , we have  $\frac{dROA}{d\lambda} < 0$  and  $\frac{dROA}{ds} < 0$ . If creditor rights are not too weak,  $\frac{d^2ROA}{d\lambda ds} > 0$ .*

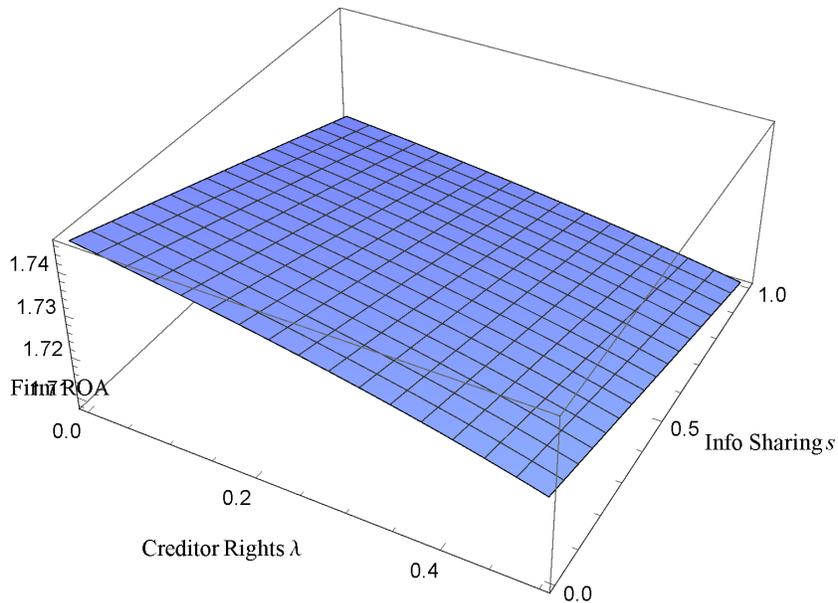

Figure 3: Firm profitability (ROA)  $Y(I)$

**Risk.** In the model, risk appears in different places. For example, if creditor rights increase, the loss given default (LGD) decreases. However, the probability of default (PD) increases because banks screen less. If we define risk as  $PD \times LGD$ , then we get

$$\text{risk} = PD \times LGD = \frac{(1-q)(1+q(1-s))(1-\gamma)}{\gamma + (1-q)(1+q(1-s))(1-\gamma)} \times (1-\lambda). \quad (9)$$

This time, let us start with discussing the easier case, which is the effect of information sharing  $s$  on risk. Because information sharing does not influence the LGD, we can focus on the effect on the PD. We have

$$\frac{dPD}{ds} = \frac{\partial PD}{\partial s} + \frac{dq}{ds} \cdot \frac{\partial PD}{\partial q}, \quad (10)$$

where Lemma 2 implies  $dq/ds < 0$ , more information sharing means less screening. Now,

$$\begin{aligned}\frac{\partial \text{PD}}{\partial s} &= -\frac{q(1-q)\gamma(1-\gamma)}{(\gamma+(1-q)(1+q(1-s))(1-\gamma))^2} < 0 & \text{and} \\ \frac{\partial \text{PD}}{\partial q} &= -\frac{(2q(1-s)+s)\gamma(1-\gamma)}{(\gamma+(1-q)(1+q(1-s))(1-\gamma))^2} < 0.\end{aligned}\tag{11}$$

There are two countervailing effects. First, the information leads to fewer bad entrepreneurs applying for loans. Second, the banks' screening gets laxer. In the specification of our numerical example, the first (direct) effect dominates, though this is not a general property. If the function  $q(s)$  has a jump somewhere, then  $dq/ds \approx -\infty$ , and the second (indirect) effect dominates.

Now, look at the effect of creditor rights. We have

$$\begin{aligned}\frac{d(\text{risk})}{d\lambda} &= \frac{d\text{PD}}{d\lambda} \cdot \text{LGD} + \text{PD} \cdot \frac{d\text{LGD}}{d\lambda} \\ &= \frac{dq}{d\lambda} \cdot \frac{\partial \text{PD}}{\partial q} \cdot \text{LGD} - \text{PD}\end{aligned}\tag{12}$$

From Lemma 2, we know that  $dq/d\lambda < 0$ , and from right above, we know that  $\partial \text{PD}/\partial q < 0$ . Therefore, depending on the relative sizes of LGD and PD, the effect of creditor rights on aggregate risk can be positive or negative. Again, in the specification for our numerical simulations, the effect is always negative, see Figure 4.

Finally, we would also like to know whether the effects of creditor rights and information sharing on risk are substitutes. In our numerical simulation, they are:  $d^2\text{risk}/d\lambda ds > 0$ .

## 5 Data and Variables of Interest

**Creditor Rights and Information Sharing Variables** The original creditor rights index was established by LLSV, but it was updated to a time series between 1978-2003 by DMS. The creditor rights index takes on integer values from 0 to 4 where larger values indicate more creditor friendly bankruptcy codes. For each of the four types of rights creditors have, an additional unit is added to the index value. DMS find that creditor rights are very sticky over time and LLSV show that they are primarily a function of legal origin. We use the most recent 2003 value of creditor rights from DMS, though the results are also robust to using the original LLSV measure.

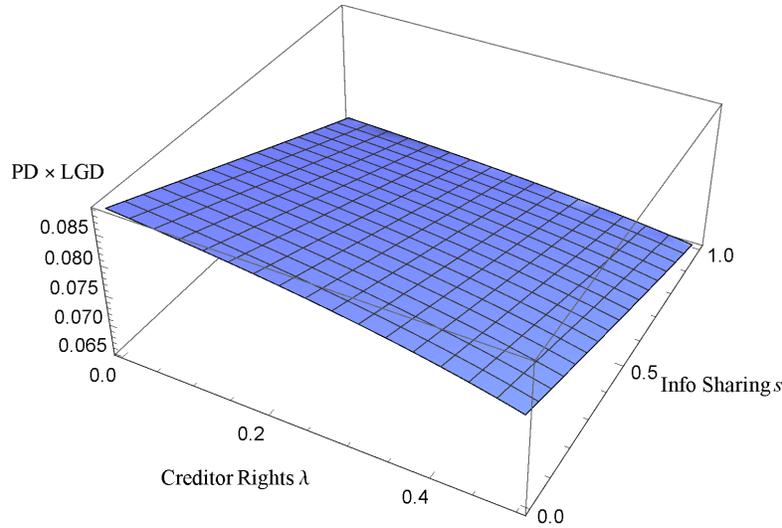

Figure 4: Firm Risk

Specifically, the first component of the creditor rights index is *Reorg*, which indicates whether restrictions, such as creditor consent, exist when a borrower files for reorganization. The second element of the index, *NoAutostay*, is whether or not secured creditors are able to seize their collateral once a reorganization petition is approved or whether the courts impose an automatic stay of assets. If there is no automatic stay of assets in place and secured creditors can immediately seize collateral, the variable *NoAutostay* is 1. If the secured creditor is paid first out of the proceeds of liquidating a bankrupt firm, the value of *Secured* is 1. The final component of the index, *Manages*, takes a value of 1 if management is removed during times of bankruptcy and an administrator is appointed by the courts to run the firm. The creditor rights index measure for each country are reported in Table 3. Both the mean and median country has a creditor rights index of two, though the individual components tend to differ between countries.

The proxy for information sharing between banks, *Depth*, comes from the World Bank. The index ranges from 0 to 6, where higher values indicates greater information sharing. There are six components of this index.

1. Both positive information and negative information are distributed.
2. Data on both firms and individual borrowers are distributed.
3. Data from retailers, trade creditors, or utilities, as well as from financial institutions are distributed.
4. More than two years of historical data are distributed.

5. Data are collected on all loans of value 1% of income per capita.
6. Laws provide for borrowers rights to inspect their own data.<sup>8</sup>

A value of one is added to the index if each component is present in either a public credit registry or a private credit bureau. The World Bank collects information regarding the Depth of information for each country annually. For the final sample of 26 countries, both the average and mean of the *Depth* variable are about five, though again, the exact type of information that is shared varies by country.

**Firm-Level Variables.** The primary firm data source for this analysis is the 2016 Amadeus Database by Bureau Van Dijk. This database has extensive data on many public and private companies within Europe, and its heterogeneity makes it ideal for testing our predictions. Importantly, the firms within this database are small, private, and likely to be impacted by the local creditor rights and information sharing environment. The Amadeus data is designed to be comparable across countries, but there are cross-country differences in the classification and disclosure requirements between countries.<sup>9</sup> Bureau Van Dijk does not introduce bias by reconstructing unreported variables. This data set has a great deal of missing information, especially for small private firms, which limits the sample. Both academics and practitioners have relied on this data for analysis in previous studies, though it is still important to bear in mind the comparability of balance sheet data across countries.<sup>10</sup>

We follow the private firm literature (Badertscher, Shroff, and White, 2013; Badertscher, Shanthikumar, and Teoh, 2016) and eliminate financial firms, firms with missing financial information, as well as firms with sales less than \$100,000 and total assets less than \$500,000. This helps alleviate the possibility that the data contained within Amadeus is unreliable for very small firms.<sup>11</sup> Additionally, because the primary variables of interest in our study are

---

<sup>8</sup>Brown, Jappelli, and Pagano (2009) construct a variant on the depth of information sharing index where component six is removed. Our results are robust to constructing this index in the same fashion.

<sup>9</sup>For example, German accounting standards place a great deal of value on conservatism, which could mean that assets of the firms within Germany are undervalued relative to asset values in other European countries. Furthermore, expenditure in research and developments is not required to be disclosed on the firm balance sheets in many countries, and Bureau Van Dijk cannot acquire data for small firms in Switzerland. However, differences in accounting practices are not unique to Amadeus and also exist in other more widely used data sets including Global Vantage and Compustat.

<sup>10</sup>An additional problem worth noting is the issue of survivorship within the Amadeus database. If a company is absent for four years, the company is deleted from the database and historical records are not obtained by Bureau van Dijk.

<sup>11</sup>This primarily affects firms contained in Italy, France, and Spain where there is very strict reporting standards for firms of all sizes.

creditor rights and information sharing, we follow HLLM and eliminate countries with a socialist legal origin.

The 2016 Amadeus database contains available firm data for the years 2006-2016. The final sample of firms consists of 4,427 public firms and 1,877,901 private firms. Table 3 shows the twenty-six European countries in the sample and the types of creditor rights that are present in each economy. Previous papers utilizing the Global Vantage database (Acharya, Amihud, and Litov, 2011; Acharya, Sundaram, and John, 2011) have only examined publicly traded companies, and previous literature has shown that there are substantial differences between public and private companies (Claessens and Tzioumis, 2006; Giannetti, 2003).

Furthermore, the relationship lending literature suggests that small firms are most likely to borrow from local banks (Berger and Hannan, 1989; Berger and Udell, 2002). The sample consists almost entirely of private firms that cannot easily access equity markets (Berger and Udell, 1998) and depend primarily on funding from commercial banks along with the equity of the principal owner (Berger and Udell, 2002). Because both the local banks and small firms are within the same economy, the small firms within this sample are the ones that are most likely to be impacted by the local creditor rights and information sharing conditions.

Firm-level variables of interest are constructed using the Amadeus database. The three primary variables of analysis in this study are firm leverage, profitability, and risk (distance to default). The total amount of borrowing ( $FDebt$ ) is the sum of non-current liabilities in long-term debt and current liabilities in loans.<sup>12</sup> The two most common ways for a firm to acquire debt is either to obtain a loan or issue debt. Since the majority of the firms are small and private, most of the debt on their balance sheet is likely bank loans, which closely links to the predictions in our model.

Total borrowing ( $FDebt$ ) scaled by total firm assets ( $FAssets$ ) is the definition of firm leverage ( $FLeverage$ ) in regressions. Leverage is winsorized at 1% in each tail. Profitability,  $ROA$ , is defined as  $EBITDA/FAssets$ . The variable  $ZScore$  represents firm risk-taking and measures number of standard deviations the firm is away from default. The  $ZScore$  for a firm-year has a numerator that is equal to the average  $ROA$  of the preceding three years plus the average ratio of capital to assets ( $CAR$ ) over the preceding three years. The denominator is the standard deviation of  $ROA$  for the preceding three years. The  $ZScore$  used in the analysis is calculated each year. The median (average) firm in our sample is 3.5787 (8.8958) standard deviations from bankruptcy.

---

<sup>12</sup>Due to data limitations, commercial paper is not included in the estimate of  $FDebt$  because the specific types of debt are unknown. However, this would bias estimates down (against our findings).

Further firm-level controls are primarily taken from Myers (1977) and Booth, Aivazian, Demirgüç-Kunt, and Maksimovic (2001). These firm-level controls include log total firm assets, *LogFAssets*, in order to control for any size effects. The variable *TanAssets* measures the percentage of total assets that are recorded as fixed assets, a proxy for collateral.

Additionally, Tobin's Q, which is the ratio of the market value of the firm's total assets to its book value, is typically an indicator of investment opportunity. However, because over 99% of firms in the sample are privately held, it is not possible to compute a market value. As a result, investment opportunities are proxied by, *Growth*, which is computed by examining the natural log of the increase in sales growth consistent with the private firm investment literature (Shin and Stulz, 1998; Lehn and Poulsen, 1989; Whited, 2006; Whited and Wu, 2006; Bloom, Bond, and Van Reenen, 2007; Asker, Farre-Mensa, and Ljungqvist, 2015; Badertscher, Shroff, and White, 2013). The amount of years since incorporation, *Age*, proxies for reputation, which is important according to Diamond (1991).<sup>13</sup>

All firm-level control variables are winsorized at the 1% level, except *ROA* and *Growth* which are winsorized at 5% to curtail the skewness and outlier influence. In total, there are 5,664,488 firm-years in the sample spanning twenty-six countries. Firm-Level variables of interest are presented in Table 4 Panel A.

Table 4 Panel A shows that many of the firm-level variables are extremely right skewed. The small number of public firms in the sample have significantly more assets than the average private firm in the sample, skewing all of the firm-level variables, except for *LogFAssets*. The median (mean) firm has a leverage of 0.1117 (0.2323), corresponding to assets of \$1.9 million (\$6.9 million) and loans of \$197,445 (\$1,540,058). Subsequent analysis will examine the impact of this right-skewedness.

**Additional Macro Controls.** A selection of macro-level controls is included for all firm-level regressions that are designed to control for the macro lending environment. These country-level variables attempt to control for differences in economic development across countries, and they are shown in Panel B of Table 4. Real Per Capita GDP and Inflation data are from the World Bank, and legal origin dummy variables (*English*, *French*, *German*, *Scand.*)<sup>14</sup> are from DMS.

---

<sup>13</sup>The firms in our sample may be fairly small, but the age variable indicates that they are not startups. The median firm has been incorporated for thirteen years, while the mean firm is about 15 years old.

<sup>14</sup>The dummy variable representing the Scandinavian legal origin is omitted from regression results because it is collinear with the other three legal origin dummy variables.

Claessens and Klapper (2005) suggest that when certain components of the creditor rights index are higher, there are more bankruptcies. However, a number of papers also suggest that it is not just the rules that are in place but the way that they are enforced that determines their implications (Bae and Goyal, 2009; Bhattacharya and Daouk, 2002, 2009). Given that one of the variables of interest is the credit friendliness of the country bankruptcy code, the practical meaning of this variable is important for us.

In each regression, we include a variety of controls designed to control for corruption (*Corruption*), government effectiveness (*Effectiveness*), quality of regulation (*Regulation*), and rule of law (*Law*), and political stability (*Stability*) to capture government stability and the degree of law enforcement. These variables are explained in Appendix B. Higher values are positive measures, indicating greater control of corruption, government effectiveness, quality of regulation, and rule of law. All variables are shown in Table 4 Panel B and winsorized at the 1% level, while Panel C displays summary statistics for the country-level variables.

## 6 Empirical Specification

**Leverage Analysis.** We start our empirical analysis focusing on firm leverage. Within the model, as creditor rights and information sharing increase, at bank loses less on bad loans. Banks then compete harder to attract larger size loans by lowering the interest rate, which leads to an increase in investment volume and firm leverage. In order to test this hypothesis, we use the following empirical model,

$$\begin{aligned} FirmLeverage_{f,c,t} = & \alpha'_1 CRights_c + \alpha'_2 Depth_{f,c,t} + \alpha'_3 CRights_c \times Depth_{f,c,t} \\ & + \alpha'_4 FirmControls_{f,c,t-1} + \alpha'_5 CountryControls_{c,t-1} + \varepsilon_{f,c,t} \end{aligned} \quad (13)$$

Industries are classified at the three-digit SIC level. Both industry and year fixed effects are included in the regressions, and errors are clustered at the country and year level for all regressions.<sup>15</sup> Firm-level controls include log firm assets (*LogFAssets*), firm profitability (*ROA*), the proxy for collateral (*TanAssets*), sales growth (*Growth*), and firm reputation (*Age*). Macroeconomic controls that vary by year include *LogGDP* and *Inflation*, along with

---

<sup>15</sup>Unfortunately, we cannot include country-level or firm-level fixed effects because the creditor rights measure is from 2003, which is the most recent year of the data provided by Djankov, McLiesh, and Shleifer (2007), while the earliest year of firm-level data included in the sample is 2006. However, as previously discussed, creditor protection is very constant over time and are likely to accurately estimate the degree of investor protection during the sample period. If the creditor rights are stable over time for a given country and country-level fixed effects are included, the direct effect would be differenced out.

the variables to capture government stability and the degree of law enforcement (*Corruption, Stability, Effectiveness, Regulation, and Law*). Finally, Cole and Turk-Ariss (2015) show that legal origin is an important determinant of bank loan ratios, so we include legal origin dummies as controls (*English, French, and German*). The model suggests that enhanced creditor protection and greater information sharing lead to larger loan sizes, indicating  $\alpha_1 > 0$  and  $\alpha_2 > 0$ . The model also predicts that there is a substitution effect between creditor rights and information sharing, which would be reflected if  $\alpha_3 < 0$ . The results of the leverage regressions are presented in Table 5.

The results of Table 5 are consistent with the theoretical model presented in Section 3. The coefficients on both *CRights* and the depth of information sharing, *Depth*, are both positive and statistically significant in columns 1-4. This indicates that stronger creditor rights and greater information sharing between banks is associated with greater firm borrowing.

Column 1 shows that when creditor rights are increased by one unit, leverage increases by .0715 on leverage. The magnitude of this estimate is huge, considering that the average (median) firm in the entire sample has a leverage ratio of 0.2323 (.1117). If information sharing is examined without creditor rights in column 2, the regression results suggest that a one unit increase in information sharing leads to an increase of .0257, also quite large. In column three, when both variables of interest are included in the model, the magnitudes of the effects on leverage only slightly decrease.

The results in Column 4 show that creditor rights and information sharing are substitutes. They also correct for the unrealistic magnitudes obtained in columns 1-3. Holding information sharing at the mean amount of 4 and examining the impact of increasing creditor rights by unit indicates that firm leverage will increase by 0.0392 ( $0.0796 - 0.0101 \times 4$ ). This is a 45% reduction in magnitude compared to the estimated effect of creditor rights on leverage that was obtained in column 1. Furthermore, if we hold creditor rights constant at the mean level of 2, this means that increasing information sharing by one unit will have an effect on leverage of 0.0057 ( $.0259 - 0.0101 \times 2$ ), which is an 80% drop in the magnitude compared to column 2. The differences in economic magnitudes depending on the regression framework suggest that it is necessary to jointly examine both variables in order to isolate the effect of each one individually on firm leverage. The fit of the model ( $R^2$ ) also improves once the interaction term is included in regression framework. As discussed in the literature review section, this result is potentially very important, because the literature focusing on creditor rights up to now is largely separate from the one on information sharing.

Column (4) indicates that adding an interaction term between creditor rights and information sharing improves the fit of the model, and the negative sign on the coefficient demonstrates

that these variables are substitutes. HLLM also focuses their bank-level analysis on the way creditor rights and information sharing jointly impact bank-level outcome variables. They find evidence suggesting that creditor rights and information sharing move in opposite directions, while their interaction effect offsetting some of the negative decision-making associated with creditor rights.

The firm-level controls presented in Table 5 indicate that firms with more assets (*LogFAssets*), a greater ability to offer collateral (*TanAssets*), and more investment opportunities (*Growth*) are more levered, while firms that are older (*Age*) are less levered. The macroeconomic controls indicate that greater real per capita GDP (*LogGDP*) and inflation lead to lower levels of firm-leverage, while greater control of corruption (*Corruption*) has a positive effect on firm leverage. The effect of rule of law (*Law*), quality of regulation (*Regulation*), government effectiveness (*Effectiveness*), and political stability (*Stability*) are inconclusive, given their coefficients switch signs and change significance depending on the regression specification. English, French, and German legal origin are also shown to be positively associated with firm leverage.

**Profitability Analysis.** As previously shown in the model, as creditor rights and information sharing increase, this causes the rate that the bank charges to decrease. As a consequence, firm investment and leverage increases. However, because the bank is screening less and earning a better return on each unit of investment, it is willing to lend to less profitable firms. Thus, higher creditor rights and information sharing should be negatively related to firm profitability. Empirically, we test this prediction in (14) and expect  $\beta_1 < 0$  and  $\beta_2 < 0$ . The model also predicts that there is a substitution effect between creditor rights and information sharing, which would be reflected if  $\beta_3 > 0$ . The results of the leverage regressions are presented in Table 5.

$$ROA_{f,c,t} = \beta'_1 CRights_c + \beta'_2 Depth_{f,c,t} + \beta'_3 CRights_c \times Depth_{f,c,t} + \beta'_4 FirmControls_{f,c,t-1} + \beta'_5 CountryControls_{c,t-1} + \delta_{f,c,t} \quad (14)$$

All controls are identical to those presented in equation 15 (13), except that, since leverage has been shown to be an important determinant of firm profitability, leverage (*FLeverage*) is included as a control. The results are presented in Table 6.

Consistent with theory, both creditor rights and information sharing are negatively and significantly related to firm profitability, as can be seen from Table 6 columns 1-4. Just as we had seen within the leverage framework, the magnitudes of both variables when examined

separately in columns 1-3 are unrealistically huge, considering the median (mean) firm ROA is .0295 (.0493).

Holding information sharing constant at the mean level of 4, a one unit increase in creditor rights leads to ROA decreasing by 0.00072. Holding creditor rights constant at the mean level of 2, a one unit increase in information sharing is associated with a decrease in profitability of 0.00258. Just as what we found in the leverage framework, when jointly examining creditor rights and information sharing, the magnitudes decrease dramatically, as compared to examining each variable individually.

**Distance to Default Analysis.** Within the model, firm risk appears in a number of different places. When creditor rights are stronger, by definition, the loss given default (LGD) of each loan goes down. However, banks screen less, which leads to more bad borrowers getting loans, indicating that the probability of default (PD) increases. These two effects move in different directions. Depending on whether the loss given default or the probability of default dominates, the effect on aggregate risk can either indicate an increase or decrease in risk. The numerical simulations suggest that the loss given default dominates, leading to a reduction in risk. Enhanced information sharing, however, means that that the banks have more information about the borrowers and reduce the fraction of bad loans within the pool (direct effect), though they also screen less (indirect effect). Within the model and numerical simulations, the direct effect dominates, indicating that the probability of default should decrease.<sup>16</sup> Empirically, we construct an aggregate risk measure at the firm-year level. The firm z-score proxies for the aggregate firm risk, that is, loss given default times the probability of default ( $LGD \times PD$ ). The z-score represents the number of standard deviations that the firm is away from bankruptcy. Larger z-scores indicate greater financial stability and decreased probability of bankruptcy. If the data are consistent with the theoretical predictions, we would expect that in equation (15),  $\gamma_1 > 0$  and  $\gamma_2 > 0$ , corresponding to both creditor rights and information sharing being associated with greater distance to default (larger z-score).

$$\begin{aligned}
ZScore_{f,c,t} = & \gamma'_1 CRights_c + \gamma'_2 Depth_{f,c,t} + \gamma'_3 CRights_c \times Depth_{f,c,t} \\
& + \gamma'_4 FirmControls_{f,c,t-1} + \gamma'_5 CountryControls_{c,t-1} + v_{f,c,t}
\end{aligned} \tag{15}$$

Our empirical results, presented in Table 7, confirm the model predictions. Columns 1-4 again show that greater levels of creditor rights and information sharing (individually or

---

<sup>16</sup>As mentioned when discussing the details of the model, all else equal banks would choose less risky firms, reinforcing the results of the numerical simulations.

jointly) have a positive impact on a firm’s distance to default, which indicates that firms are less risky. In column 3, once both variables of interest are included in the regression, both regression coefficients drop by more than 30% as compared to those in columns 1-2.

As done in previous sections, if we hold information sharing constant at 4, the results in column 4 indicate that a one unit increase in creditor rights increases z-scores by 0.185, indicating that the firm is 0.185 standard deviations further away from bankruptcy. An increase in information sharing indicates that z-scores increase by 0.142 when creditor rights are held constant and the interaction effect is considered. The median (mean) firm has a z-score of 3.5787 (8.8958), indicating that not only are these results statistically significant but also economically meaningful.

## 7 Robustness Results

As pointed out in Section 5, the Amadeus dataset is extremely heterogenous. This heterogeneity is a strength of the database, since it provides the opportunity to focus on the firms that most closely match the model. However, since the data is so skewed to the right, a few extremely large firms may determine our results.

A key assumption of the model presented in Section 3 is that the entrepreneurs are approaching banks for loans. This makes both the local firm and local bank exposed to the local creditor rights and information sharing environment. The model does not incorporate alternative financing possibilities, such as obtaining equity or partaking in the international bond market. Firms with such opportunities may respond differently to local creditor rights. Furthermore, public firms file more reports and have a higher level of transparency than private firms, so it could be the case that information sharing is less important for these firms. Our first robustness check eliminates the public firms in our sample. The results are shown in Table 8.

The regression framework in Panel A, examining *FLeverage*, contains controls identical to those reported in Table 5, while the framework for Panels B and C, focusing on *ROA* and *ZScore* respectively, are identical to those presented in Tables 6 and 7. The results in Table 8 are practically identical to those presented in Tables 5, 6, and 7, indicating that the public firms are not driving our results.

Within the literature, the positive effect of creditor rights on firm borrowing resolves the paradoxical conclusions reached by DMS, HLLM, and AAL. DMS find that there is more

private credit in economies with greater creditor rights, and HLLM find that increased creditor rights lead to greater bank risk-taking, which could mean that they are lending to a wider pool of borrowers. However, AAL and Acharya and Subramanian (2009) show that greater creditor protection are associated with decreased leverage for public firms. The findings within Table 5 indicate that it is the private firms in an economy that are benefiting from enhanced creditor protection and borrowing more.

However, we take our analysis one step further in our next robustness check. Private firms not able to acquire financing through the equity market are not necessarily exposed to the local creditor rights environment. It could be the case that large private firms can obtain debt across country lines or obtain syndicated loans consisting where all syndicate members are not from their home country, causing a question as to whether creditor protection laws are applicable in practice. It is most likely that the largest firms in our analysis may have the opportunity to obtain financing through international debt markets or have alternatives to local bank loans.

In order to address this possibility, we remove the largest 10% of firms in the sample, as determined by asset size. The results reported in Table 9 are all quantitatively similar to those from Tables 5 to 7 except that the magnitudes on the estimated coefficients are consistently larger, indicating that both creditor rights and information sharing have a greater effect on smaller firms.<sup>17</sup>

This same robustness check also applies to a number of different questions. One such question is how the differences of ownership structures may differ between countries and how this relates to creditor rights. It could be possible that the holding companies can obtain more favorable financing terms through wholesale debt markets. This group of firms would be less reliant on bank loans. Using the Amadeus database, we cannot determine which firms are held by holding companies and which are not. However, holding companies typically do not hold firms as small as the ones that primarily make up our sample. By removing the top 10% or 20% of observations, we remove the group of firms that is also most likely to be held by a holding company.

We also control for the size of the equity market in Table 10. This addresses the possibility that the equity market is driving our results, and it also adds an additional proxy for financial market development. Columns 1-3 present the results for robustness checks when the dependent variable is firm leverage, profitability, and z-score respectively. These regressions are quantitatively similar to those presented in Column 4 of Table 5, Table 6, and

---

<sup>17</sup>Our results hold even if we remove the largest 20% of firms, tables available upon request.

Table 7 respectively. The data on stock market capitalization is acquired from the World Bank, though the data is unavailable for a number of country-years, reducing our sample. In Table 11, we perform similar analysis only controlling for the ratio of private credit to GDP. Again, the results are quantitatively similar.

In subsequent analysis, we consider the fact that countries with larger amounts of firms are biasing our results. For each country, every year, we pick a random sample of 100 firms with assets between \$0.5, the lower bound of our sample selection, and \$1 million. Then, we pick another 100 firms with assets between \$1 million and \$1.5 million and for each bucket thereafter, up to \$6 million. This essentially forces our panel to be more balanced and helps us adjust for the differences in reporting standards between firms. The differences are quantitatively similar to previous regressions and are presented in Table 12.<sup>18</sup>

We also conduct a number of robustness checks that are applicable only to certain outcome variables. We construct leverage net of cash and examine the log of the z-score measure. Results are quantitatively similar to those reported in tables 5 and 7. Additionally, because the calculation of the z-score involves averages over time, autocorrelation could be a problem and bias our results. Instead, we construct three separate three-year non-overlapping windows, and the model predictions are robust. We also address the idea that certain firms target “zero leverage,” indicating that they do not wish to incur debt. The right-skewedness of leverage and firm debt reported in Table 5 suggest that this could be true. Within the data, it is difficult to determine which firms target “zero leverage.” However, if we remove the group of 5% or 10% of firms with the lowest leverage in our sample, the results are robust.

Additionally, we examine alternative measures of creditor rights and information sharing. Instead of using the DMS measure of creditor rights, we perform analysis using the measure from LLSV. In our model, information sharing is between banks, not between banks and borrowers. The sixth component of the information sharing index, laws provide for borrowers rights to inspect their own data, does not directly apply to our model framework, since it is information sharing between banks and borrowers. Brown, Jappelli, and Pagano (2009) also drop this component from their analysis. Whether we examine a five or six component depth of information sharing index, all of our results are robust.

In a final robustness check, Klapper, Laeven, and Rajan (2006) suggest removing a number of industries where the activity is country specific (such as uranium mining) and utilities, which tend to be largely state-owned in Europe. After removing all of the industries that they outline, our results still hold.

---

<sup>18</sup>This is an alternative to a weighted regression. In the context of the theory model, smaller firms are more likely to be most directly impacted. However, weighting by something like the inverse of assets may put too much weight on the small firms in the sample that may have issues with data reliability.

## 8 Conclusion

A large literature examines cross-country differences in creditor rights and information sharing, and the impact on capital markets, bank lending, as well as firm borrowing. Previous literature has found that enhanced creditor rights have associated with a number of positive outcomes, including greater lending, cheaper debt, as well as greater economic growth. However, creditor rights are largely established at the time of a country's inception, are sticky over time, and are not converging to a common level. On the contrary, information sharing is improving over time and has the ability to help countries with low levels of creditor rights realize some of the positive outcomes associated with higher levels.

*Theoretically*, this our paper shows that greater levels of creditor rights and information sharing are associated with greater firm leverage, lower firm profitability, as well as greater distance to default. Within the model, the two variables are also shown to be substitutes.

*Empirically*, we use over 1.8 million public and private firms within Europe and confirm the model predictions. Our empirical results show that not only do creditor rights and information sharing interact, but this interaction is a necessary component to understanding the impact of each individual variable. These results are robust to a number of further specifications. By focusing on private firms, we can closely link the empirical results to the theoretical model, as well as explain some of the existing paradoxes within the existing creditor rights and information sharing literature.

The theoretical and empirical results within this paper are suggestive of a policy implication. Since creditor rights and information sharing are robust substitutes, countries with low levels of creditor protection could consider increasing the collection and transmission of information sharing between banks, if they desire the outcomes associated with greater levels of creditor rights.

## A Proofs

**Proof of Lemma 1 (Loan Demand).** Taking the derivative of the implicit function (2) with respect to  $R$  yields

$$2I'(R)Y'(I) + II'(R)Y''(I) - 1 = 0,$$

$$I'(R) = \frac{1}{2Y'(I) + Y''(I)}. \quad (16)$$

The loan demand is thus downward sloping,  $I'(R) < 0$ . We are also interested in the second derivative,  $I''(R)$ , and therefore derive the first order condition once more,

$$0 = (2Y'(I) + IY''(I))I''(R) + I'(R)^2(3Y''(I) + IY'''(I)),$$

$$I''(R) = -I'(R)^2 \frac{3Y''(I) + IY'''(I)}{2Y'(I) + IY''(I)} < 0. \quad (17)$$

Hence, the loan demand is downward sloping and concave. ■

**Proof of Lemma 2 (Screening Intensity).** We first show that  $dq^*/d\lambda < 0$ . (6) implicitly defines  $q^*$ . Let  $\Gamma$  denote the left-hand side of equation (6). Then

$$\frac{dq^*}{d\lambda} = -\frac{\partial\Gamma/\partial\lambda}{\partial\Gamma/\partial q^*}. \quad (18)$$

At  $q = 0$ , we have

$$\Gamma(q = 0) = (1 - \gamma)(r - \lambda) - c'(0). \quad (19)$$

We have assumed that  $c'(0)$  is small, for example  $c'(0) = 0$ . Therefore,  $\Gamma(q = 0) > 0$ . Also, per definition,  $\Gamma(q = q^*) = 0$ . Therefore, by a purely geometric argument,  $\Gamma(q)$  at  $q^*$  must cross the 0 from above, hence  $\partial\Gamma/\partial q < 0$  at  $q = q^*$ . We also have

$$\partial\Gamma/\partial\lambda = -(1 + q(1 - s))(1 - \gamma) < 0, \quad (20)$$

which implies that  $dq^*/d\lambda < 0$ . Second, we must show that  $dq^*/ds < 0$ . To learn how information sharing influences the screening decision, take

$$\begin{aligned} \partial\Gamma/\partial s &= q(1 - \gamma)[c'(q) - (r - \lambda)] \\ &= -\frac{q\gamma(1 - \gamma)(r - \lambda)}{1 + q(1 - s)(1 - \gamma)}, \end{aligned} \quad (21)$$

which implies that  $dq^*/ds < 0$ .

Finally, turn to the cross derivative. In general, we have

$$\frac{d^2q}{d\lambda ds} = \frac{\Gamma_q (\Gamma_\lambda \Gamma_{qs} + \Gamma_s \Gamma_{q\lambda} - \Gamma_q \Gamma_{\lambda s}) - \Gamma_s \Gamma_\lambda \Gamma_{qq}}{\Gamma_q^3} \quad (22)$$

where indices stand for derivatives with respect to that variable. It can easily be shown that the signs of the terms in the bracket differ even in a numerical example, so it is futile to try and lead a general proof. Therefore, we use the additional assumption that creditor rights  $\lambda$  are not too small, that is, close enough to the return  $r$ .

For exactly  $\lambda = r$ , banks do not lose money on bad loans, hence they do not screen,  $q^* = 0$ . This is independent of information sharing  $s$ . Hence for  $\lambda = r$ , we have  $dq/ds = 0$ . We have just shown that for weaker creditor rights (smaller  $\lambda$ ), the loan rate  $q$  is increasing in  $s$ . Hence a lower  $\lambda$  makes  $q$  increase more in  $s$ : the cross derivative  $d^2q/d\lambda ds$  is negative. ■

**Proof of Lemma 3 (Loan Rate).** We start with the first inequality. Let  $\Delta$  denote the left-hand side of (8) in the symmetric equilibrium,

$$\begin{aligned} \Delta &= \gamma(I(R) - A) + \gamma I'(R)(R - r) \\ &\quad - (1 - q)(1 + q(1 - s))(1 - \gamma) - \gamma)(r - \lambda) I'(R) = 0. \end{aligned} \quad (23)$$

We want to know how  $R^*$  reacts upon changes in parameters, first of all creditor rights  $\lambda$ . The implicit function theorem gives us

$$\frac{dR^*}{d\lambda} = -\frac{d\Delta/d\lambda}{\partial\Delta/\partial R^*}. \quad (24)$$

Here,  $\partial\Delta/\partial R = \partial\Pi_1/\partial R_1^2$  must be negative, otherwise  $R^*$  would not maximize, but minimize expected profits.

The derivative  $d\Delta/d\lambda$  consists of the partial derivative plus the indirect effect through  $q^*$ ,

$$\frac{d\Delta}{d\lambda} = \frac{\partial\Delta}{\partial\lambda} + \frac{\partial\Delta}{\partial q^*} \cdot \frac{dq^*}{d\lambda}. \quad (25)$$

We now look at the separate terms. First,

$$\frac{\partial\Delta}{\partial\lambda} = (1 - q)(1 + q(1 - s))(1 - \gamma) I'(R) < 0 \quad (26)$$

because all but the last factors are positive. Second,

$$\begin{aligned} \frac{\partial\Delta}{\partial q^*} &= [(2q(1 - s) + s)(1 - \gamma)(r - \lambda) - (1 - \gamma)(1 - s)c(q^*) - (1 + q(1 - s)(1 - \gamma))c'(q^*)] I'(R) \\ &= -(1 - s)(1 - \gamma)((1 - q^*)(r - \lambda) + c(q^*)) I'(R) > 0. \end{aligned} \quad (27)$$

Finally, we have already shown that  $dq^*/d\lambda < 0$  in the above section. Consequently,  $dR^*/d\lambda < 0$ .

We go on to prove the second statement. The implicit function theorem gives us

$$\frac{dR^*}{ds} = -\frac{d\Delta/ds}{\partial\Delta/\partial R^*}. \quad (28)$$

with again  $\partial\Delta/\partial R^* < 0$  and

$$\frac{d\Delta}{ds} = \frac{\partial\Delta}{\partial s} + \frac{\partial\Delta}{\partial q^*} \cdot \frac{dq^*}{ds}. \quad (29)$$

Here, we already know that  $\partial\Delta/\partial q^* > 0$  and  $dq^*/ds < 0$ . It remains to check

$$\frac{\partial\Delta}{\partial s} = q(1-\gamma)((1-q)(r-\lambda))I'(R^*) < 0 \quad (30)$$

because all factors are positive, except the last. Summing up,  $dR^*/ds < 0$ .

We now come to the third statement. In general, we have

$$\frac{d^2R}{d\lambda ds} = \frac{\Delta_q(\Delta_\lambda\Delta_{qs} + \Delta_s\Delta_{q\lambda} - \Delta_q\Delta_{\lambda s}) - \Delta_s\Delta_\lambda\Delta_{qq}}{\Delta_q^3} \quad (31)$$

where indices stand for derivatives with respect to that variable, for example  $\Delta_s = d\Delta/ds$  as in (29). It can easily be shown that the signs of the terms in the bracket differ even in a numerical example, so it is futile to try and lead a general proof. Therefore, we use the additional assumption that creditor rights  $\lambda$  are not too small, that is, close enough to the return  $r$ .

For exactly  $\lambda = r$ , banks do not lose money on bad loans, hence they do not screen,  $q^* = 0$ . There is perfect competition between banks, thus  $R = r$ , which is independent of information sharing  $s$ . Hence for  $\lambda = r$ , we have  $dR/ds = 0$ . For weaker creditor rights (smaller  $\lambda$ ), the loan rate  $R$  is decreasing in  $s$  (see Lemma 3). Hence a lower  $\lambda$  makes  $R$  decrease more in  $s$ : the cross derivative  $d^2R/d\lambda ds$  is thus positive. ■

**Proof of Proposition 1 (Leverage).** The first two statements are direct consequences of the definition of leverage,  $\text{Lev} = (I - A)/A = I/A - 1$ , Lemma 1, and Lemma 3. For the third statement, we have

$$\begin{aligned} \frac{d^2}{d\lambda ds}\text{Lev} &= \frac{d^2\text{Lev}}{dR^2} \cdot \frac{dR}{ds} \cdot \frac{dR}{d\lambda} + \frac{d\text{Lev}}{dR} \cdot \frac{d^2R}{d\lambda ds} \\ &= \frac{d^2I}{A^2 dR^2} \cdot \frac{dR}{ds} \cdot \frac{dR}{d\lambda} + \frac{dI}{A dR} \cdot \frac{d^2R}{d\lambda ds} \end{aligned} \quad (32)$$

Because of Lemma 1, the first and second derivative of  $I$  with respect to  $R$  are negative. Because of Lemma 3, both  $dR/d\lambda$  and  $dR/ds$  are negative. If also  $d^2R/d\lambda ds > 0$ , then both parts of the sum are negative, and consequently  $d^2\text{Lev}/d\lambda ds < 0$ . ■

**Proof of Proposition 2 (Profitability/ROA).** The first two statements are direct consequences of the definition of the ROA,  $Y(I(R))$ , Lemma 1, Lemma 3, and the assumption that  $Y'(I) < 0$ . Third, we want to establish that  $d^2Y(I(R))/d\lambda ds > 0$ . We have

$$\frac{d^2}{d\lambda ds} Y(I(R)) = (Y''(I) I'(R)^2 + Y'(I) I''(R)) \cdot \frac{dR}{ds} \cdot \frac{dR}{d\lambda} + Y' \cdot I' \cdot \frac{d^2 R}{d\lambda ds}. \quad (33)$$

Because  $Y' < 0$ ,  $Y'' < 0$ ,  $I' < 0$  and  $I'' < 0$ , the sign of the bracket term seems to be ambiguous. The other two factors are both negative, hence the sign of the first part of the sum seems to be ambiguous. The second part of the sum is negative times negative times positive, which is positive. Now remember (16) and (17),

$$I'(R) = \frac{1}{2Y'(I) + Y''(I)},$$

$$I''(R) = -I'(R)^2 \frac{3Y''(I) + IY'''(I)}{2Y'(I) + IY''(I)} < 0.$$

Substituting this into (33), the bracket term of (33) becomes

$$\frac{IY''(I)^2 - Y'(I)(Y''(I) + IY'''(I))}{(2Y'(I) + Y''(I))^2 (2Y'(I) + IY''(I))} \quad (34)$$

If a function  $f(x)$  is decreasing and concave, then  $x f'(x) < f(x) - f(0)$  for  $x > 0$  (the absolute of  $x f'(x)$  is larger, though). Consequently, if  $Y'(I)$  is decreasing and concave (which it is by assumption), then  $IY''(I) < Y'(I) - Y'(0) = Y'(I)$  because of the assumption that  $Y'(I) \approx 0$ . Because  $Y'''(I) < 0$ , the numerator of the fraction is negative. The denominator is also negative, hence the complete fraction is positive. Consequently, the cross derivative of (33) is positive. ■

## B Variable Descriptions

Variable	Definition	Source
Corruption	This indicator measures the extent to which public power is exercised for private gain, including both petty and grand forms of corruption, as well as “capture” of the state by elites and private interests. Higher values indicate more control over corruption.	Kaufmann, Kraay, and Mastruzzi (2008)
Creditor rights ( <i>CRights</i> )	An index aggregating the four components of the creditor rights as originally proposed by La Porta, Lopez-de Silanes, Shleifer, and Vishny (1998) and extended by DMS. This index ranges from zero to four where higher values indicate greater levels of investor protection. The four components of the creditor rights index are the variables Restrictions; NoAutostay; Secured; and Manages: The value of 2003 from Djankov, McLiesh, and Shleifer is used in this study.	DMS

Depth of Information Sharing ( <i>Depth</i> )	An index that measures the information sharing within an economy. A value of one is added to the index when each of the following characteristics is present. The index ranges from 0 to 6, where higher values indicates greater information sharing. There are six components of this index. 1) Both positive information and negative information are distributed 2) Data on both firms and individual borrowers are distributed. 3) Data from retailers, trade creditors, or utilities, as well as from financial institutions are distributed 4) More than two years of historical data are distributed. 5) Data are collected on all loans of value 1% of income per capita. 6) Laws provide for borrowers rights to inspect their own data. A value of one is added to the index if each component is present in either a public registry or a private bureau.	World Bank
<i>EBITDA</i>	Earnings before depreciation and taxes	
<i>Effectiveness</i>	This variable indicates the quality of public services, the quality of the civil service, and the degree of its independence from political pressures, the quality of the civil service and the degree of its independence from political pressures, the quality of policy formulation and implementation, and the credibility of the government's commitment to such policies. Higher values mean higher quality of public and civil service.	Kaufmann, Kraay, and Mastruzzi (2008)
Firm Assets ( <i>FAssets</i> )	Total firm assets. The data are winsorized at 1% in each tail and reported in U.S. dollars.	Amadeus
Firm Leverage ( <i>FLeverage</i> )	Ratio of firm loans to firm assets truncated at 1 and winsorized at 1% in each tail	Amadeus
Firm Debt ( <i>FDebt</i> )	Sum of on-current liabilities in long-term debt and current liabilities in loans (in US dollars) winsorized at 1% in each tail	Amadeus
Sales Growth ( <i>Growth</i> )	Log increase in sales winsorized at 1% in each tail	Amadeus
Inflation	Inflation as measured by the consumer price index reflects the annual percentage change in the cost to the average consumer of acquiring a basket of goods and services that may be fixed or changed at specified intervals, such as yearly. The Laspeyres formula is generally used, and the data are winsorized at 1% in each tail.	World Bank
Rule of Law ( <i>Law</i> )	Rule of law measures the extent to which agents abide by and have confidence in the rules of society. In particular, this measure captures the quality of contract enforcement, the police, and the courts, as well as the likelihood of crime and violence. Higher values indicate stronger law and order.	Kaufmann, Kraay, and Mastruzzi (2008)
Legal Origin ( <i>English</i> ), ( <i>German</i> ), ( <i>French</i> ), and ( <i>Scandinavian</i> )	Dummy variables for English (Eng), German (German), French (Fren); Scandinavian (Scandinavian), or Socialist (Socialist) legal origin	DMS
Log Firm Assets ( <i>LogFAssets</i> )	Log total assets (in US dollars) winsorized at 1% in each tail	Amadeus

Management Removal ( <i>Manages</i> )	One component of the creditor rights index that takes the value of one if during the reorganization of a business, an official is appointed by the court, or by the creditors, takes responsibility for operating the business. The firm management does not retain administration of its property pending the resolution of reorganization. This variable also takes a value of one, if the firm does not keep the administration of its property pending the resolution of the reorganization process. Otherwise, this variable is zero.	DMS
No Automatic Stay of Assets ( <i>NoAutostay</i> )	One component of the creditor rights index that equals one if the reorganization process does not impose an automatic stay on assets of the firm upon filing the reorganization petition and creditors are able to seize their collateral after the reorganization petition is approved. This variable is zero otherwise.	DMS
Priv. Credit to GDP ( <i>privatecreditgdp</i> )	Domestic credit to private sector (% of GDP)	World Bank
Government Regulation ( <i>Regulation</i> )	This variable represents the ability of the government to formulate and implement sound policies and regulations that permit and promote market competition and private-sector development. Higher values mean higher quality of regulation	
Restrictions on Reorganization ( <i>Reorg</i> )	This component of the creditor rights index has a value of 1 if the reorganization procedure imposes restrictions such as creditor's consent or minimum dividend for a debtor to be able to file for reorganization. If a country does not have such a restriction, this component takes a value of zero.	DMS
Profit ( <i>ROA</i> )	EBITDA/Total Assets winsorized at 5% in each tail	Amadeus
Secured Creditor Paid First ( <i>Secured</i> )	One component of the creditor rights index that takes a value of one if secured creditors are ranked first in the distribution of the proceeds that result from the disposition of the assets of a bankrupt firm, opposed to other creditors such as employees or government. If non-secured creditors such as the government or employees are given priority, this component takes a value of zero.	DMS
Government Stability ( <i>Stability</i> )	This indicator measures the perceptions of the likelihood that the government will be overthrown or destabilized or overthrown by violent or unconstitutional methods, including violence or terrorism. Higher values mean more stable environments.	Kaufmann, Kraay, and Mastruzzi (2008)
Stock Market Capitalization ( <i>Stockmarketcap</i> )	Market capitalization of listed domestic companies (% of GDP)	World Bank
Tangible Assets ( <i>TanAssets</i> )	Fixed assets scaled by total assets winsorized at 1% in each tail	
Distance to Default ( <i>Zscore</i> )	The firm z-score indicates the number of standard deviations that the firm is away from bankruptcy where higher values indicate the that firm is less risky. The z-score numerator is equal to the average ROA of the preceding three years plus the average ratio of capital to assets over the preceding years. The denominator is the standard deviation of ROA for the preceding three years.	Amadeus

Table 3 describes the type of firms that are used for subsequent analysis. Column 1 shows the twenty-six countries examined, and Columns 2 and 3 show the breakdown of the number of firms in each country that are private and public. Column 4 indicates the total number of firms from each country analyzed, and Column 5 indicates the amount of creditor rights that exist within each country. The creditor rights index ranges from 0 to 4 where a greater index value indicates more investor protection. The four components of the creditor rights include creditor consent is required for borrowers to file for reorganization, creditors can automatically seize collateral once the reorganization petition is approved, the secured creditor is paid first out of the proceeds of liquidating a bankrupt firm, and either creditors or the courts have the ability to appoint a manager to run the firm during the bankruptcy process. Columns 5 and 6 indicate the value of information sharing in each country in 2006 and 2014, the start and end of the sample period. The index ranges from 0 to 6, where higher values indicates greater information sharing. There are six components of this index. 1) Both positive information and negative information are distributed 2) Data on both firms and individual borrowers are distributed. 3) Data from retailers, trade creditors, or utilities, as well as from financial institutions are distributed 4) More than two years of historical data are distributed. 5) Data are collected on all loans of value 1% of income per capita. 6) Laws provide for borrowers rights to inspect their own data. A value of one is added to the index if each component is present in either a public registry or a private bureau. Variables are defined in Appendix B.

Table 4 shows the firm-level (Panel A), country-year level (Panel B) and country-level variables (Panel C) for analysis. In Panel A, *FirmLeverage* is the ratio of firm loans to firm assets. *FAssets* represents total firm assets in US Dollars, and *FLoans* represents total firm loans in US dollars. *LogFAssets* is total assets in log form, while *Growth* is computed by examining the natural log of the increase in sales growth. *TanAssets* is the ratio of tangible assets to total assets, and *Age* is years since the firm incorporated. *ROA* is defined as the ratio of *EBITA* to *FAssets*. The *ZScore* calculates the number of standard deviations the firm is from bankruptcy and is calculated over a three-year window. It is defined as the sum of the average *ROA* and capital asset ratio divided by the standard deviation of *ROA*. The *ZScore* is the average( $ROA_{t-2}$ ,  $ROA_{t-1}$ ,  $ROA_t$ ) plus the average( $CAR_{t-2}$ ,  $CAR_{t-1}$ ,  $CAR_t$ ) divided by  $\sigma(ROA_{t-2}, ROA_{t-1}, ROA_t)$ . Panel B shows the country-year variables that represent depth of information sharing (*Depth*), inflation (*Inflation*), Real Per Capita GDP in log form (*LogGDP*) as well as variables to proxy for the degree of enforcement for a given country year. These enforcement variables are from Kaufmann, Kray, and Mastruzzi, 2008 and represent control of corruption (*Corruption*), political stability (*Stability*), government effectiveness (*Effectiveness*), quality of regulation (*Regulation*), and rule of law (*Law*). Panel C shows the country-level creditor rights (*CRights*) variable and dummy variables indicating legal origin (*English*, *French*, *German*, *Scandinavian*, and *Socialist*). Variables are defined in Appendix B.

Table 5 reports the OLS regression results for the dependent variable firm leverage (*FLeverage*), defined as the ratio of firm loans to firm assets. The sample consists of 1,882,328 public and private firms within twenty-six countries shown in Table 3. Columns 1-4 report full sample OLS regression results, accounting for industry fixed effects at the three-digit SIC level and year fixed effects. All independent firm-level and country-level variables are lagged by one year. Standard errors are adjusted for cluster effects at the country and year levels. Variables are defined in Appendix B. Significance is denoted by \*  $p < 0.10$ , \*\*  $p < 0.05$ , and \*\*\*  $p < 0.01$ .

Table 7 reports the OLS regression results for the dependent variable firm profitability (*ZScore*). The *ZScore* is the  $\text{average}(ROA_{t-2}, ROA_{t-1}, ROA_t) + \text{average}(CAR_{t-2}, CAR_{t-1}, CAR_t)$  divided by  $\sigma(ROA_{t-2}, ROA_{t-1}, ROA_t)$ . The sample consists of 1,882,328 public and private firms within twenty-six countries shown in Table 3. Columns 1-4 report full sample OLS regression results, accounting for industry fixed effects at the three-digit SIC level, and year fixed effects. Standard errors are adjusted for cluster effects at the country and year levels. All independent firm-level and country-level variables are lagged by one year. Variables are defined in Appendix B. Significance is denoted by \*  $p < 0.10$ , \*\*  $p < 0.05$ , and \*\*\*  $p < 0.01$ .

<i>N</i>	5,646,779	5,646,779	5,646,779	5,646,779

Table 8 reports the results for the 1,887,901 private firms and 5,646,779 private firm-year observations. Panel A reports the coefficients on the creditor rights (*CRights*), depth of information sharing (*Depth*), and interaction (*CRights \* Depth*) for when firm leverage (*FLeverage*) is the dependent variable. The firm-level, country-level, and fixed effects are identical to those presented in Table 5 but are unreported. Panel B reports select coefficients when the dependent variable is firm profitability (*ROA*), and unreported controls are consistent with those presented in Table 6. The dependent variable in Panel C is Firm ZScore (*ZScore*). The *ZScore* is the  $\text{average}(ROA_{t-2}, ROA_{t-1}, ROA_t) + \text{average}(CAR_{t-2}, CAR_{t-1}, CAR_t)$  divided by  $\sigma(ROA_{t-2}, ROA_{t-1}, ROA_t)$ . The controls in Panel C are identical to those presented in Table 7. Columns 1-4 report full sample OLS regression results, accounting for industry fixed effects at the three-digit SIC level and year fixed effects. Standard errors are adjusted for cluster effects at the country and year levels. All independent firm-level and country-level variables are lagged by one year. Variables are defined in Appendix B. Significance is denoted by \*  $p < 0.10$ , \*\*  $p < 0.05$ , and \*\*\*  $p < 0.01$ .
