ABSTRACT

Fiscal Federalism in Germany: Stabilization and Redistribution Before and After Unification

We provide empirical estimates of the risk-sharing and redistributive properties of the German federal fiscal system based on data from 1970 until 2006, with special attention to the effects of German unification. We find that tax revenue sharing between the states and the federal government and the fiscal equalization mechanism (Länderfinanzausgleich) together reduce differences in per-capita state incomes by 36.9 percent during period 1970 to 1994. After the full integration of East German states into the mechanism in 1995, the redistributive effects increase slightly to about 38.6 percent. With respect to the insurance effect of the German fiscal system, our results indicate that the federal fiscal system offsets 47 percent of an asymmetric shock to state per-capita incomes. This effect has significantly decreased after the inclusion of the East German states in 1995. Furthermore, we find that the German fiscal system provides almost perfect insurance for state government budgets against asymmetric revenue shocks; also, its redistributive effect with regard to the tax resources available to state governments is very strong.

Submitted 27 March 2009

1 Introduction

In a world with imperfect capital markets, fiscal arrangements for risk sharing and redistribution of income across different regions of a country or the states of a federation can play an important role for consumption smoothing (Boadway 2004; Bucovetsky 1998; Lockwood 1999). Such arrangements have received considerable interest in recent years, both in the context of designing the fiscal framework of the European Monetary Union (EMU) and in the design of new federal systems in developing countries (Boadway and Shah, 2007). One branch of this literature considers the role of such arrangements for redistribution and consumption risk-sharing among consumers living in different regions of a country or federation who are exposed to region-specific shocks (e.g., Atkeson and Bayoumi, 1993; Wildasin, 1996; Persson and Tabellini, 1996a, 1996b; Bucovetsky 1998; Lockwood, 1999, Boadway, 2004). The other branch of the literature starts with Mundell's (1961) analysis of optimum currency areas and, following Kenen (1969), argues that in a world of sticky wages and prices fiscal transfer arrangements among regions or states sharing the same currency can stabilize regional aggregate demand and employment by redistributing income between regions exposed to asymmetric cyclical shocks (European Commission, 1977a, 1977b; Sachs and Sala-i-Martin, 1992; von Hagen, 1992; Goodhart and Smith, 1993; Bayoumi and Masson, 1995; Athanasoulis and van Wincoop, 1998). This literature has played an important role in the design of EMU and its main point is nicely summarized by the former president of the European Commission, Jacques Delors (see Delors, 1989 p.89), in the blueprint for the EMU:

“... in all federations, the different combinations of federal budgetary mechanisms have powerful “shock-absorber” effects dampening the amplitude either of economic difficulties or of surges in prosperity of individual states. This is both the product of, and the source of the sense of national solidarity which all relevant economic and monetary unions share.”

The empirical work in this area has focused on the extent to which fiscal flows between different regions or between the regions and the central government offset regional differences in economic fluctuations at cyclical frequencies. Most of it has analyzed the US fiscal system. Sachs and Sala-i-Martin (1992) estimate that the tax and transfer flows between the US federal government and the states offset between 33 and 40 percent of a region-specific shock and, thus, provide considerable stabilization. von Hagen (1992) pointed out the importance of distinguishing between the (short-term) stabilization and (long-term) redistribution functions of federal fiscal systems.³ Later studies adopted this distinction, and their empirical results commonly suggest that the contribution of the US fiscal system to stabilizing regional incomes

³ In this paper, we use the terms *stabilization* and *insurance* interchangeably.

is smaller than what Sachs and Sala-i-Martin estimated, ranging between 10 and 30 percent. At the same time, the redistributive effects are large.⁴ Empirical studies for other countries, including Canada, France, Italy, report similar results.⁵

This paper provides new evidence on the stabilization and redistributive properties of the federal fiscal system in Germany. We focus on fiscal equalization which operates through vertical transfers between the states and the federal government and horizontal transfers among the states. Germany is a particularly interesting case in this context, because, like Canada and unlike the United States, it has an explicit, constitutional, and formula-based mechanism for fiscal equalization which redistributes tax revenues among the states and the federal government. Yet, empirical evidence on properties of the German federal fiscal system remains scant. This is most likely due to the intricacies of the rules of the system, data problems and the structural breaks connected with German unification in the early 1990s. Only Pisani-Ferry et al. (1993) study the stabilizing properties of German fiscal equalization, and they do so based on a methodological approach which is very different from the rest of the literature. They find that the fiscal system stabilizes between 34 and 42 percent of asymmetric shocks affecting individual states.

Our paper studies the empirical properties of fiscal equalization in Germany based on the same approach the literature mentioned above has used for other countries. This facilitates comparisons between equalization in Germany and other countries. The paper makes three contributions to the literature. First, it provides an analysis of the stabilizing and redistributive properties of all stages of fiscal equalization. This allows us to show the contributions of the different vertical and horizontal transfers. Second, our analysis covers the pre-unification period, during which only the 10 West German states participated in the system, and the post-unification period, which extended the system to the five East German states and the city state Berlin. It thus provides evidence for the effects of unification on fiscal equalization in Germany. Third, we analyze the properties of German fiscal equalization as an instrument for redistributing tax revenues among state governments and insuring state government budgets against asymmetric shocks in addition to the assessment of its redistribution and stabilization properties with regard to regional disposable incomes, which are commonly considered in the literature. This sheds new light on the economic interpretation of fiscal equalization.

⁴ See Goodhart and Smith, 1993; Bayoumi and Masson, 1995; Méritz and Zumer, 1998, 2002, van Wincoop (1995), and Kletzer and von Hagen (2001) for a detailed review of this literature.

⁵ With regard to Canada, however, Smart (2004) points out that, due to lags in the calculation of the equalization grants, fiscal equalization may actually be destabilizing.

Fiscal federalism literature commonly regards equalization as an arrangement aiming at improving the welfare of representative consumers living in the different regions of a federation. The object of the analysis is, therefore, the per-capita amount of resources available for these consumers, both directly and indirectly through the government budgets of the states where they live. The implicit assumption behind this is that the mechanisms of fiscal federalism are designed by representatives of the citizen-voters as part of the federal constitution.⁶ In Germany, however, the federal constitution calls for fiscal equalization, but the particular mechanism used for this purpose and its frequent changes over time are regulated by federal legislation negotiated between the federal and the state governments. They are, therefore, the outcome of intergovernmental negotiations in which the representatives of the regional and the federal governments are fighting over the distribution of tax revenues (Renzsch, 1991; see also Pitlik et al. 2001; Renzsch, 1989; and Rothweiler, 1972). If the politicians involved were interested in the size and stability of the government budgets over which they command, fiscal equalization may have become an instrument for redistributing and stabilizing government revenues rather than the total resources available for regional consumers. This would amount to the same, if government revenues are simply proportional to private incomes, but it need not do so otherwise, e.g., when private incomes and government revenues are exposed to different shocks. Therefore, we pursue both lines of inquiry in this paper.

Our main results can be summarized as follows. First, the German federal fiscal system provides considerable redistribution of disposable per-capita income between states. It reduces pre-equalization differences in disposable state incomes by about 37 percent. This is comparable in magnitude to other federations. Most of it is achieved through tax sharing between the states and the federal government. Second, until 1994, the German federal fiscal offset about 47 percent of asymmetric shocks to state incomes and thus provided significant stabilization. Again, most of this is achieved through tax sharing with the federal government, while equalization through horizontal transfers among the states offset only about 10 percent of asymmetric shocks to state disposable incomes. Since the inclusion of the new East German states in the system, the insurance effect has declined to 19 percent. While large and small states do not benefit from the stabilizing function before 1995, city states enjoy almost perfect stabilization of their disposable incomes. After 1995, the overall stabilizing function decreases, but now positively affects all states, independent of size. Third, German unification has left the overall degree of redistribution unchanged, but it has changed the contributions of the different stages of the system. Significantly, it has led to more redistribution among the West German states. Fourth, the

⁶ See e.g. Persson and Tabellini (1996a,b).

German federal fiscal system provides for significantly more redistribution of state tax revenues than state disposable incomes, reducing pre-equalization differences by about 75 percent. Fifth, the system provides (almost) perfect insurance of state revenues against asymmetric shocks.

Fiscal equalization is not the only mechanism of regional income redistribution in Germany. Federal health insurance, unemployment insurance and pension systems also provide powerful mechanisms for the same purpose. Several empirical studies have taken a broader perspective of the issue and analyzed the stabilizing properties of the fiscal system as a whole for the regions of Germany. Using the methodology suggested by Asdrubali et al (1996), Büttner (2002) finds that, during the period from 1970 to 1997, the entire German fiscal system smooths only around 15 percent of state-specific shocks to the disposable income of households in Germany and that fiscal equalization contributes 6.8 percent to this.⁷ He does not consider the effects of German unification. Kellermann (2001) uses German data from the same time period and distinguishes explicitly between pre- and post-unification data. The sample from 1970 to 1990 (“pre-unification”) includes only the 10 states of the former West Germany; the sample from 1992 to 1997 (“post-unification”) includes all 16 states of the unified Germany. Based on the same methodology as Büttner (2002), she finds that public transfers smooth over 40 percent of shocks to state income. More recently, Jüßen (2006) investigates risk sharing and redistribution in post-reunification Germany based on a very disaggregated data set of 271 labor market regions. He finds that the German fiscal system provides no insurance against asymmetric income shocks over and above what is provided by private capital markets. Furthermore, the fiscal system turns out to be very effective in decreasing long-term differences in regional incomes leading to convergence of regional incomes towards the national average. Jüßen’s data, however, cannot identify the effects of fiscal equalization.

In this paper, we focus more narrowly on the tax sharing between the states and the federal government and the explicit equalization mechanism in Germany. These are interesting in their own right, first, because of their constitutional status. Second, these are the kinds of mechanism that have been discussed in the context of EMU. Third, our analysis facilitates comparison of Germany’s arrangements with those of other federations with explicit mechanisms for equalization. We leave a broader study of the regional stabilization provided by the entire German fiscal system to another paper.

⁷Of the remainder, about 5 percent of income smoothing comes from the federal unemployment insurance, and around 4.3 percent from the federal mandatory pension system. In a paper that focuses on the risk sharing properties of Germany’s federal unemployment insurance with respect to regional labor income, Kurz’s (2000) empirical investigation leads to a very similar result. In her study, about 8 percent of a shock to regional labor income is smoothed by the federal unemployment insurance. Additionally, she finds that unemployment insurance has only a small effect on long-term redistribution of regional labor incomes.

The rest of this paper proceeds as follows. In section 2, we explain the design of the federal fiscal system in Germany. Section 3 presents the data and provides some descriptive statistics. In section 4, we present our empirical methodology and our main empirical results. Section 5 concludes.

2 The Federal Fiscal System in Germany

Germany is a federation of 16 states, of which 10 together with West-Berlin formed the Federal Republic of Germany from 1949 to 1990. Five East German states became additional members in 1990, and the (now united) city of Berlin also became a state at that time.⁸

The country's federal fiscal system is an attempt to reconcile two conflicting principles which are present in the German constitution (Renzsch, 1991). On the one hand, the state governments are autonomous and independent of each other and of the federal government in their budgetary policies, and they are individually responsible for carrying out their tasks effectively.⁹ On the other hand, the German constitution requires the states to assure "*uniform living standards throughout the territory of the federation*".¹⁰ With regard to tax revenues, the constitution mandates the federation to assure that all state governments have the financial means to supply their citizens with public goods and services of similar quantity and quality.¹¹ The tension between these two principles arises from the large differences in the economic strength and, hence, the tax capacity of the individual states. These differences call for transfers among the states to achieve a greater degree of equality. In addition, the federal government can pay transfers to individual states in order to improve their fiscal conditions.

All taxes in Germany are collected by the states. This is a consequence of the fact that the federal government does not have its own administration to execute its policies; the German constitution mandates the states to execute all federal policies as their own concerns. All major taxes are legislated by federal law and the state governments participate in the legislative procedure through the Upper House of the German parliament (*Bundesrat*), the members of which are representatives of the state governments, not elected by the citizens. As a result, individual state governments cannot change the parameters of the main taxes and there is no tax competition among the states.¹² Tax legislation including the assignment of revenues to the

⁸ For a list of states, see table 9. West-Berlin had a special status in pre-unification Germany and was not part of the fiscal equalization mechanism before unification.

⁹ Grundgesetz (German Constitution) Articles 29, 30, and 109:1.

¹⁰ Grundgesetz, Article 72:2, Para 3, and Artikel 106:3, Para 2.

¹¹ Grundgesetz, Article 107, see also Jung (2008).

¹² Some tax competition occurs at the local level through business taxes.

federal and the state level is part of a broader process of political negotiations and trades between the federal and the state governments (Pitlik et al, 2001; Renzsch, 1991).

Germany's Constitution of 1949 assigned the revenue of all taxes of unambiguous local incidence to the states, among them personal and corporate income taxes and business taxes, leaving the federal government only with the revenue from a sales tax, which was later replaced by value-added tax (VAT), and some minor taxes. In order to secure it with a sufficient revenue base, the federal government initially received a third of the revenues from personal and corporate income taxes collected by the states; this share gradually climbed to 35 percent until 1969, with the states receiving a share of the revenues from VAT in return. Personal and corporate income taxes and VAT are called *Gemeinschaftsteuern* (shared taxes).

The 1949 Constitution called for subsequent federal legislation to regulate the sharing of revenues among the states and the federal government. This was achieved by the Fiscal Constitution Act (*Finanzverfassungsgesetz*) of 23 December 1955. It instituted a horizontal tax revenue sharing arrangement among the states (*Länderfinanzausgleich*) covering the revenues from all state taxes plus half of the local taxes accruing to the municipalities. The Act guaranteed every state a minimum of 88.75 percent of the national average per-capita revenue from this base from 1956 onwards. By 1959, this minimum had been raised to 91 percent. In 1967, the federal government started paying supplementary transfers (*Bundesergänzungszuweisungen*) to states with low tax capacities to further even out the remaining discrepancies.

The federal fiscal system was reformed in 1969. Half of the revenue from corporate income tax, 42.5 percent of the revenue from personal income tax, and 70 percent of the revenue from VAT were assigned to the federal government. The horizontal tax revenue sharing arrangement was changed to guarantee each state a minimum of 95 percent of the national average per-capita revenues from all state taxes and half of the revenue from local taxes. Over the next two decades, the federal share of personal and corporate income tax remained virtually unchanged, but the federal share of VAT was adjusted numerous times and fluctuated between 70 in 1970 and 65 percent in 1990. After German unification in 1990, the VAT share was reduced to 63 percent by 1994. In 1995, Germany's federal fiscal system was reformed again to fully integrate the East German states. This entailed a significant change in the formula for distributing VAT income. The federal share of VAT revenue dropped from 63 percent in 1994 to 56 percent in 1995, and then to 50.5 percent in 1996 and 1997, the remainder going to the state governments. Since 1998, local governments also receive a share of around two percent of VAT revenue taken from the states' share. In more recent years, the federal share has stabilized at around 53 percent and the state governments' share at around 45 percent.

Subsequently, we refer to *Länderfinanzausgleich (LFA)* as fiscal equalization. It is a formula-based mechanism and comes after the splitting of the revenues from joint taxes between the federal government and the states. The latter already involves considerable redistribution, since the incidence of joint taxes is very different across states. LFA itself is a three-stage process. At the first stage, the states' share of total national VAT revenues is redistributed among the states. 75 percent of the total VAT revenues attributed to the states are distributed among the states on an equal per-capita basis. The remaining 25 percent of the total VAT revenues are used to make payments to states with per-capita revenues from all state taxes of less than 92 percent of the federal average. If the amount available for redistribution is not large enough, the transfers are scaled back proportionally. If the amount available is more than what is needed, the remainder is distributed among the financially strong states on a per-capita basis.

At the second stage of LFA, tax capacities and resource needs are calculated for all states. Tax capacity is determined by the sum of state tax revenues¹³ and 50 percent of the local taxes collected on a state's territory. Resource needs are calculated as the average per-capita state tax revenues in Germany multiplied by the population of the respective state.¹⁴ The difference between tax capacity and resource needs determines whether a state pays or receives additional, horizontal transfers under the LFA. Financially weak states receive payments lifting them to at least 92 percent of federal average per-capita tax revenues. If a state's revenues are between 92 and 100 percent of the federal per capita average, it receives transfers that amount to 37.5 percent of that difference. Until 1995, states with revenues exceeding 102 percent of the national average paid contributions to LFA. For per-capita revenues between 102 and 110 percent of the federal average, the contribution was equal to 70 percent of the difference, for per-capita revenues above 110 percent of the federal average, the contribution was 100 percent of the difference between the state's revenues and the federal average. As a result, the differences in per-capita tax revenues among the states after redistribution ranged between 95 percent and 104.4 percent of the federal average.

The 1995 reform of LFA modified these rules. For per-capita revenues between 100 and 101 percent of the national average, the contribution is now 15 percent of the difference, for per-capita revenues between 101 and 110 percent of the federal average, it is 66 percent of the difference, and for per-capita revenues above 110 percent of the federal average, it is 80 percent of the difference. Contributing states must be left with at least 95 percent of the average per-capita revenues after redistribution. Together with the supplementary payments, all states have at least 99.5 percent of the average per capita revenues.

¹³This sum now includes the VAT revenue assigned to a state in the first stage.

¹⁴At this stage, the special financial needs of the city states Hamburg and Bremen (and later Berlin) are recognized by attributing them with larger than actual populations.

At the third stage of LFA, the federal government makes payments to the states to further reduce the differences in per-capita tax revenues. These “supplementary transfers” are general-purpose grants which are computed on the basis of special financial needs and the per capita VAT revenue of the financially weak states. The 1995 reform greatly increased the role of these payments in order to provide the East German states with sufficient fiscal resources. Furthermore, it introduced a number of new supplementary grants targeting smaller West German states, all East German states, as well as the West German states Bremen and Saarland, which were facing difficulties with the transition from the old equalization system.¹⁵ The discretionary nature of these new vertical grants has reduced the transparency that previously characterized German fiscal equalization (Guihéry, 2001).

To summarize, the federal fiscal system in Germany involves the following steps: (1) Splitting of tax revenues from joint taxes between the federal government and the state governments. (2) LFA, which has three stages, (2A) horizontal redistribution of VAT revenues, (2B) horizontal equalization payments, and (2C), vertical supplementary transfers from the federal to state governments.

3 Data and Descriptive Statistics

In this section, we provide a more detailed description of the variables used in the panel data analysis to estimate the amount of risk sharing and redistribution of tax revenues provided by German fiscal equalization. We construct two different data sets: The first consists of annual data of the 10 West German states from 1970 to 1994. Comparable data do not exist for East Germany, and the German Democratic Republic was not organized as a federal system. The second data set contains annual data of all 16 German states covering the period from 1995 to 2006. Both panels are balanced. We follow previous literature and construct *state income* by adding up net national income at factor prices and all tax revenues with incidence in the state. These tax revenues include all federal (*Bundessteuern*), state (*Landessteuern*), and local taxes (*Gemeindesteuern*), plus the taxes shared between all three levels of government (*Gemeinschaftsteuern*).

We use four different versions of disposable state income corresponding to the four stages of the German federal fiscal system. The first includes state income as defined above minus all federal taxes, the federal share of the shared taxes, and the federal share of the local business tax (*Gewerbesteuerumlage*). The result is the sum of net national income at factor prices plus all state and local taxes that remain with either the state or the local governments. The law on LFA governs the next two steps in the redistribution of tax revenue. In the first step, VAT

¹⁵ These two states had received bail-outs for their excessive debts in the early 1990s.

revenues are redistributed among the states. The second definition of disposable state income thus includes VAT transfers received (+) or paid (–) from or to other states. In the second step of LFA, states make further transfer payments among each other. Hence, the third definition of disposable state income adds or subtracts transfers from the second definition. Finally, the fourth definition of disposable income includes any additional federal grants paid to a state (*Bundesergänzungszuweisungen*).

For the period from 1970 to 1994, we use national accounting data provided to us by the Statistical Office of Baden-Württemberg. Data on tax revenues before and after redistribution come from publications of the German Federal Statistical Office (Statistisches Bundesamt 1977, 1989, 2000). Very detailed tax data on the local, state, and federal level for the years 1991 to 1994 were provided by the Statistical Office of Baden-Württemberg. Data on VAT redistribution and state-to-state transfers are provided in the annual publications of the Upper House of Parliament (Bundesrat, various years). All nominal variables for this sample period are deflated with the West German GDP deflator with base year 1991.

For the period from 1995 to 2006, we use national accounting data provided online by the German federal and state statistical offices (Statistisches Landesamt Baden-Württemberg, 2008) which is based on a standardized European Union methodology (ESVG1995). Very detailed tax data on the local, state, and federal level for the years 1995 to 2002 is provided by the Statistical Office of Baden-Württemberg; data for the years 2003 to 2006 is available online from the German Federal Statistical Office (Statistisches Bundesamt, various years). Again, data on VAT redistribution and state-to-state transfers is published annually by the Upper House of Parliament (Bundesrat, various years). All data for the period from 1995 to 2006 is deflated by state-specific GDP deflators with base year 1991. Note that, because of the change in accounting methods, the data for the two sub-periods are not directly comparable.

Table 1 reports some basic statistics for West Germany and the sample period from 1970 to 1994. In 1970, real GDP per capita among the 10 West German states ranges from 82 to 171 percent of the federal average, with the standard deviation amounting to around 16 percent of the federal average. Over the next two and a half decades, the range narrows slightly to 83 and 167 percent of the average. The standard deviation from the average remains virtually unchanged with 15 percent of average per capita real GDP. It is noteworthy that per-capita VAT transfers and state-to-state transfer receipts do not change significantly as a percentage of average GDP over time. State-to-state transfer payments even fall both in absolute value and as a percentage of GDP. However, federal transfers noticeably went up (in both absolute value and as a percentage of GDP), particularly after German unification.

[Table 1 about here]

In Table 2, we report these same basic statistics for the data set from 1995 to 2006, when all 16 states were included in LFA. Looking at per capita real GDP, the gap between the poorest and richest states appears to be narrowing over time. Not unexpectedly, transfer payments – especially from VAT revenue – increased significantly compared to the earlier time period as a result of including the much poorer East German states in the fiscal equalization mechanism.

[Table 2 about here]

Tables 3 and 4 present the same statistics for the East and West German states separately during the period 1995 to 2006. The tables show, first, the marked economic inequality between these two groups. Average net national income per capita in 2006 was about 78 percent larger in West Germany than in East Germany. This gap actually widened over the 11 years under consideration. In 2006, the largest per-capita GDP in an East German state was still considerably smaller than the smallest per-capita GDP in a West German state. Tax capacity, measured as average tax revenue per capita is about 160 percent larger in West Germany than in East Germany. Second, the tables show that East German states are net receivers in LFA with average per-capita horizontal transfers increasing from 229 to 271 euros. Average per-capita horizontal payments in West Germany increase from 70 to 78 euros over the same period. At the same time, average per-capita federal grants to East German states increase from 416 to 603 euros, while federal grants paid to West German states fall from 48 to a mere 10 euros.

4 Redistribution and Stabilization

4.1. Methodology

Méltz and Zumer (2002) review the various approaches to estimating the stabilization and redistributive properties of federal fiscal systems proposed in the literature and present an encompassing model which facilitates comparison across different studies. We apply their approach to Germany. Let $X_{i,t}$ be the ratio of per-capita state income in state i at time t and the national average per-capita income at time t . Furthermore, let $Y_{i,t}$ be the ratio of per-capita *disposable* state income in state i at time t and the national average disposable income per capita. For our purposes, X_{it} refers to state income before and Y_{it} to state income after the application of the different stages of the federal fiscal system. Let variables without time indices, X_i and Y_i , denote the sample period averages, Méltz and Zumer start from the following equation:

$$Y_{i,t} = \alpha_d + \beta_d X_i + \beta_s (X_{i,t} - X_i) + e_{i,t}; \quad (1)$$

$$i = 1, \dots, M; t = 1, \dots, T$$

In equation (1), $e_{i,t}$ is a stochastic disturbance. The coefficient β_d describes the effect of a change in the relative long-run average state income on the relative long-run average disposable state income. A coefficient of $\beta_d=1$ implies no redistribution at all, while $\beta_d =0$ implies “full redistribution,” as a change in relative state income does not affect disposable state income. Thus, $(1- \beta_d)$ gives the degree of redistribution achieved by the stage of fiscal equalization under consideration. Furthermore, the coefficient β_s relates deviations of relative state income at time t from the relative long-run average state income to deviations of relative disposable state income from its relative long-run average and describes the stabilization aspect of the federal fiscal system. Again, $(1-\beta_s)$ indicates the degree of stabilization provided by the fiscal system. Mélitz and Zumer decompose equation (1) into two parts to illustrate this point:

$$Y_i = \alpha_d + \beta_d X_i + v_i, \quad (2)$$

$$Y_{it} - Y_i = \alpha_s + \beta_s (X_{it} - X_i) + u_{it} \quad (3)$$

where v_i and u_{it} are random disturbance terms. Equations (2) and (3) define the two regressions we use to determine the degrees of redistribution and stabilization achieved by fiscal equalization in Germany. Note that equation (2) uses the cross section only. This might be a problem if the state economies had grown with very different trend growth rates during the sample period, which, however, was not the case. We estimate equation (2) by OLS and equation (3) using a panel estimator with robust standard errors to correct for heteroskedasticity and serial correlation of the errors.

4.2 Results for State Income

4.2.1. Redistribution

Table 5A presents the results of estimating equation (2), where $1-\beta_d$ corresponds to the degree of redistribution. The table reports the standard errors of the estimates together with an indication of statistical significance. Note that the latter refers to the Null of $\beta_d = 0$ or $(1- \beta_d) = 1$.

For the time period from 1970 to 1994, we find that the degree of redistribution provided by Germany’s federal fiscal system ranges from 31.4 to 36.9 percent, depending on which elements of the system are included. The most redistributive element is the transfer of the federal government’s share of taxes to the federal government. It reduces differences in per-capita disposable state income by 31.4 percent. This is lower than von Hagen’s (1992) result for the US of 47 percent, but in the same range as Melitz and Zumer’s (2002) and Bayoumi and Masson’s (1995) results for Canada. The contribution of the horizontal VAT redistribution and

transfers together is only 5.2 percent, mainly from the redistribution of VAT revenue. The contribution of vertical transfers from the federal government to states to redistribution is negligibly small.

After the inclusion of the East German states in LFA in 1995, the degree of redistribution at the stage of tax sharing with the federal government falls to 25 percent, while the contribution of VAT redistribution increases to 9.4 percent. Overall, transfers among the states have become much more important as an instrument for income redistribution after 1995. Vertical federal grants now contribute about 2.6 percent of redistribution.

In table 5B, we repeat the regressions for the later period, but we now ask to what extent the federal fiscal system leads to redistribution of income among the West and the East German states separately. We do this by using the East and the West German averages respectively as reference levels for state income instead of the national average. The table shows two interesting features. First, both the transfer of the federal tax share and the redistribution of VAT revenues have become significantly more redistributive among the West German states compared to the earlier time period. Overall, the federal fiscal system now eliminates 63 percent of the differences in per-capita incomes among the West German states compared to 37 percent before 1995. Thus, the relatively poor West German states have benefitted greatly from the inclusion of the East German states in the system. Second, the degree of redistribution is much lower among the East German states. Overall, it is only about half as large as the degree of redistribution among West German states and about two thirds of the degree of redistribution achieved at the national level. After 1995, the federal fiscal system is more effective in closing the gap between East and West German states than among East German states.

[Tables 5A and 5B about here]

4.2.2 Stabilization

Next, we turn to estimating equation (3). Our results are presented in tables 6A and 6B. We pool our data for the German, West German, and East German samples, but we also distinguish stabilization effects by state size.¹⁶ Let us first focus on our pooled samples in table 6A. In the period from 1970 to 1994, the degree of stabilization ranges between 34.8 percent and 46.7 percent. The contribution of the horizontal transfers is around 10 percent. While the redistribution of VAT revenue contributes 3.3 percent of stabilization, horizontal transfer payments between states contribute the largest part, namely 6.9 percent. Federal grants to states play the smallest role with 1.7 percent.

¹⁶ For the categorization of states by state size, see table 9.

[Table 6A about here]

For the period from 1995 to 2006, the stabilization properties of the federal fiscal system decrease considerably to 19.4 percent. This decrease is due entirely to the decreased effect of tax revenue sharing between the states and the federal government. In contrast, the contribution of horizontal transfers and the effect of supplementary federal grants remain about the same.

In columns 3 to 5 and 8 to 10 of table 6A, we separate the German states into large states, small states, and city states and ask to what extent the stabilization properties are different for states of different size. The table reports the stabilization effect for large states' incomes ("large") and the *additional* stabilization effects for small states ("small") and city states ("city"). The negative coefficients indicate that, in the pre-unification period, the federal fiscal system had a slight but significant destabilizing effect on the state incomes of large states. All of this destabilizing effect comes from the transfer of the federal government's share of tax revenues (-9.8 percent). In contrast, LFA has a small stabilizing effect, so that the overall effect is reduced to around negative 6.7 percent.

In the post-unification period, tax sharing with the federal government has a slightly stabilizing effect on state income for large states. Together with the later stages of equalization the entire system now has a significant albeit small stabilizing effect of around 17 percent for the large states. Note that the definition of an asymmetric shock here is relative to the average income for all of Germany rather than for West Germany alone.

In the pre-unification period, there was no additional stabilizing effect on the incomes small states, while asymmetric shocks to the incomes of city states were almost completely stabilized. For the post-unification period, table 6A suggests that the incomes of both small and city states are shielded from asymmetric shocks to the same extent as those of large states. However, when we look at the stabilizing properties for West German states alone, table 6B indicates that city states are much better protected against asymmetric shocks than large states. The additional stabilization effects for small states are positive but not statistically significant. Altogether, the results show that the stabilizing properties are different for states of different size and that city states benefit more in terms of stabilization than large and small states.

In table 6B, we perform similar exercises for the West and East Germany sub-samples separately in the post-reunification period. The results for the pooled data for West Germany show that the stabilizing effect of the fiscal system (31.1 percent) is lower after the inclusion of the East German states into the system. The largest contribution comes from tax revenue sharing

between the federal government and the West German states (16.2 percent), followed by VAT redistribution which has a stabilizing effect of about 11.4 percent.

For East Germany, we distinguish between so-called area states (Brandenburg, Mecklenburg-Vorpommern, Saxony-Anhalt, Saxony, and Thuringia) and the city state of Berlin. As table 6B shows, the stabilizing effect of the fiscal system for Berlin is indistinguishable from that for the other states. Overall, about 15 percent of asymmetric shocks get smoothed. Tax sharing with the federal government has a small, stabilizing effect on state income (around 5 percent). LFA delivers the largest contribution with about 10 percent.

In sum, our results show that the federal fiscal system provides much less insurance against asymmetric shocks to state disposable incomes since 1995 compared to the earlier period.

[Table 6B about here]

4.3. Results for State Tax Revenues

4.3.1. Redistribution

In this section, we consider the properties of Germany's federal fiscal system in a different dimension. Rather than asking to what extent it leads to a redistribution and insurance of per-capita disposable incomes, we ask to what extent it serves to redistribute and insure per-capita state government revenues. While the previous sections have focused on the importance of the system for consumers living in the different states of Germany, we now focus on the role it plays for governments. The methodology remains the same with the exception that "income" now refers to state government tax revenues. Recall that our concept of tax revenues is more comprehensive than the revenues considered for the purposes of fiscal equalization in Germany. Thus, in the regressions below, we are not just reproducing the formulas applied at the various stages of the system. Instead, we estimate its effects on total state government tax revenues.

Tables 7A and 7B show the results for redistribution of state tax revenues. Before 1995, almost 60 percent of all revenue differences are eliminated at the stage of sharing tax revenues with the federal government. VAT redistribution adds another 15 percent; state-to-state transfers 3.5 percent. Federal grants actually increased revenue inequality among the states.

From 1995 on, the relative importance of tax sharing and LFA changed dramatically. Tax sharing only eliminates 40.7 percent of income differences, while VAT redistribution adds 32.2 percent and state-to-state transfers add 4.5 percent. Federal grants contribute virtually nothing to the redistribution of tax revenues. Overall, the system has become slightly more redistributive than before including the East German states. These results indicate that fiscal

equalization plays a much more significant role for redistributing tax revenues among governments than for redistributing income among citizens.

[Table 7A about here]

In table 7B we look at the redistributive properties of the federal fiscal system among the West and East German states separately after German unification. We find that the overall redistributive effects of the fiscal system are quite large for both groups (West: 89.2 percent; East: 67.8 percent), but smaller for East Germany. Tax sharing with the federal government has very different effects for both subgroups; but tax sharing and VAT redistribution taken together eliminate about 75 percent of the differences in state tax revenues. However, state-to-state transfers have opposite effects on state tax revenues in West and East Germany. They add about two percent to the redistribution effect in the West, but increase inequality in tax revenues in the East by about 15 percent. Overall, the degree of redistribution among West German states has increased by about 18 percent when comparing the period before and after unification. This is due entirely to the effect of federal grants at the last stage of LFA, and it indicates that the relatively poor states in West Germany have benefitted significantly from the 1995 reform of the federal fiscal system

Among the East German states, tax sharing with the federal government has only a small redistributive effect. VAT transfers eliminate 65 percent of differences in per-capita state tax revenues, but the horizontal transfers increase revenue inequality. Federal transfers compensate part of that latter effect. Overall, fiscal equalization eliminates 68 percent of the differences in per capita tax revenues among East German state governments. This is less than the corresponding effect among West German states.

[Table 7B about here]

4.3.2. Stabilization

Tables 8A and 8B show our results for insurance against asymmetric state tax revenue shocks.

[Table 8A about here]

In the pooled data before 1995, tax sharing with the federal government absorbs 63 percent of all asymmetric shocks to state tax revenues among the West German states. The subsequent stages of fiscal equalization adds more insurance, and the system including federal grants provides perfect insurance against such shocks. Distinguishing by state size reveals that

tax sharing absorbs about 28 percent of asymmetric shocks in large and small states, but almost 70 percent in city states. At the later stages of fiscal equalization, the overall effect for small and city states increases to almost perfect insurance.

After 1995, the federal fiscal system is somewhat less effective. The entire system still absorbs a remarkable 87 percent of asymmetric shocks to state tax revenues. Tax sharing with the federal government provides about 40 percent of the insurance, and VAT redistribution provides an additional 44 percent. Horizontal state-to-state transfers contribute about 10 percent. Federal grants now weaken the insurance effect by about 7 percent. When we control for state size, our results further suggest that the insurance provided to states at each stage does depend on their size. Except for the last stage, city states receive more insurance than large states.

Finally, we split our sample into East and West German states again and investigate the stabilization properties of the fiscal system for these subgroups separately (table 8B).

[Table 8B about here]

For West Germany, the overall fiscal system absorbs about 90 percent of asymmetric shocks to tax revenues, with the largest contribution coming from VAT redistribution with about 45 percent. Federal grants are again slightly destabilizing. When we distinguish by state size, it turns out that tax sharing is stabilizing for all states (20 percent). VAT redistribution absorbs an extra 55 percent for small and large states, but almost an extra 67 percent for city states. After state-to-state transfers, city states' tax revenues are significantly better insured than those of large and small states (large and small: 70.1 percent; city: 96.9 percent). The magnitude and differences (due to state size) of the insurance effect remain similar, with the difference between small and city states narrowing down to about five percent. Thus, after 1995, large and small states receive less insurance against asymmetric revenue shocks than city states in West Germany.

For East Germany, the results are less conclusive. In the pooled data, the tax sharing with the federal government and the first two stages of LFA together provide almost perfect insurance against asymmetric revenue shocks. However, the federal grants at the last stage of LFA have a destabilizing effect in this dimension and reduce the insurance effect to 69.2 percent. The distinction between small states and the city state of Berlin suggests that the fiscal system may provide less insurance for Berlin than for the other five East German states, but the effects are not statistically significant. Also, the federal grants seem to have a much more destabilizing effect on Berlin than on the other states.

5 Conclusion

Our analysis explores the redistributive and the stabilizing properties of the federal fiscal system in Germany, using data from 1970 to 2006. The system features a formula-based mechanism redistributing tax revenues between the states and the federal government and among the states. It is an outflow of the constitutional mandate to secure equal living conditions for all citizens in the country. To the best of our knowledge, ours is the first study analyzing both stabilization and redistributive properties of the fiscal system of pre-unification Germany. It is also the first study directly comparing the effectiveness of the German fiscal system pre- and post-unification.

We find that the federal fiscal system achieves significant degrees of redistribution of income and of stabilization of asymmetric shocks to state incomes in Germany. Most of this is achieved by the sharing of tax revenues between the states and the federal government at the first stage of equalization. However, the system is much more effective in eliminating differences in state tax revenues and in shielding state budgets from the impact of asymmetric revenue shocks. This suggests that the politicians who negotiated fiscal equalization since the beginning of the Federal Republic cared more about its implications for state governments than for private households in their regions. Future research should address the question to what extent this focus on state budgets rather than household incomes distorts the welfare effects of fiscal equalization. Another important question is, what incentive effects a system creates that eliminates all differences in per-capita revenues across state governments and completely shields budgets against the effects of state-specific economic shocks.

Furthermore, we find that the redistributive effect of the federal fiscal system has slightly increased since the inclusion of the East German states, and that it equalizes incomes and tax revenues among West German states much more strongly than before. In this sense, relatively poor West German states are among the winners of the reforms of fiscal equalization that came into effect in 1995. Obviously, German unification has not only led to large fiscal transfers from the Western to the Eastern part of the country. It has also increased transfers among the West German states. There is also a slight decline in the degree of insurance against asymmetric shocks to state tax revenues provided to large West German states, while the degree of insurance provided to small and city states remains the same. A suggestive interpretation is that, in the negotiations between the federal and the state governments of that reform, the political representatives of the relatively poor West German states managed to forge a successful coalition with the representatives of the East German states. This is consistent with the observation that all relatively poor West German states fall into the categories of small and city

states (see table 9) and that the bargaining power of these states in the Upper House of Germany's parliament is larger than that of the large West German states (Pitlik et al., 2001).

Recent research on the stabilizing functions of fiscal equalization was stimulated by the creation of a monetary union in Europe. A common argument in the debate over EMU has been that the monetary union needs a mechanism for paying transfers between member states in different stages of the business cycle. Our empirical results suggest that the stabilization provided by the horizontal transfers among the states of Germany is rather limited. Most of the stabilization achieved by fiscal equalization in Germany comes from transferring tax revenues from the states to the federal government. Since Europe does not have a government of a size comparable to today's national governments, that is hardly an option for EMU. Germany's example suggests that horizontal fiscal equalization alone is not a promising alternative.

Notes: * significant at 10%; ** significant at 5%; *** significant at 1%. The clustered standard errors in parentheses pertain to β_s . 1970-1994: 250 observations; 1995-2006: 120 observations.

The regression equation is equation (3) in the text and a modification where the RHS variable is interacted with dummies for small and city states.

† In this column, we report the coefficient estimate $(1 - \beta_s)$ of the stabilization effect of the fiscal system on state income for a large state, the omitted state size category in the regression. The reported coefficient in the small (city) column represents the differential for small (city) states to the stabilization effect in large states (in the *large* column). For example, the stabilization effect for a small state would be the sum of the coefficients in the *large* and *small* column.

Table 6B: Stabilization of state income in Germany, 1995-2006. With interactive dummies for state size.
