This Discussion Paper is issued under the auspices of the Centre's research programme in **Industrial Organization and International Trade**. Any opinions expressed here are those of the author(s) and not those of the Centre for Economic Policy Research. Research disseminated by CEPR may include views on policy, but the Centre itself takes no institutional policy positions.

The Centre for Economic Policy Research was established in 1983 as a private educational charity, to promote independent analysis and public discussion of open economies and the relations among them. It is pluralist and non-partisan, bringing economic research to bear on the analysis of medium- and long-run policy questions. Institutional (core) finance for the Centre has been provided through major grants from the Economic and Social Research Council, under which an ESRC Resource Centre operates within CEPR; the Esmée Fairbairn Charitable Trust; and the Bank of England. These organizations do not give prior review to the Centre's publications, nor do they necessarily endorse the views expressed therein.

These Discussion Papers often represent preliminary or incomplete work, circulated to encourage discussion and comment. Citation and use of such a paper should take account of its provisional character.

ABSTRACT

R&D Cooperation and Spillovers: Some Empirical Evidence*

Our results on the relationship between R&D spillovers and cooperation in R&D suggest that it is necessary to distinguish different aspects of external information flows. We construct firm-specific measures of incoming spillovers and appropriability from survey data on Belgian manufacturing firms. Incoming spillovers measure the importance of publicly available information for the innovation process of the firm. Appropriability is defined as the effectiveness of several protection mechanisms for appropriating the benefits of successful innovations. The decision to cooperate with research institutes is mainly affected by the level of incoming spillovers, while appropriability plays an important role for cooperating with suppliers or customers. Furthermore, we analyze what determines the levels of incoming spillovers and appropriability, including a possible simultaneous relation with cooperative agreements in R&D.

NON-TECHNICAL SUMMARY

Successful innovation depends on the development and integration of new knowledge in the innovation process. Part of this knowledge will reach the firm from external sources. One challenge facing the literature has been the measurement of these information flows or 'spillovers' between firms and gauging their effect on different innovation management decisions by the firm. The contribution of this paper is twofold. First, we attempt to clarify the concept of spillovers and their measurement. Throughout the Paper, we will distinguish between *incoming spillovers*, which affect the rate of innovation of the firm, and *outgoing spillovers* which affect the ability of the firm to appropriate the returns from innovation. Second, we use these measures of spillovers to analyze the decision of firms to engage in cooperative agreements in R&D. To the best of our knowledge, this is the first study that empirically investigates the relation between cooperation in R&D and spillovers. This is surprising given the extensive theoretical literature which focuses on this relationship.

Our results on the relationship between firm-specific spillovers and cooperation measured at the firm level suggest that *incoming* and *outgoing* spillovers have important and separately identifiable effects: firms with higher incoming spillovers and lower outgoing spillovers, i.e. better appropriation, have a higher probability of cooperating in R&D. Zeroing-in on the type of partner in the cooperative agreements allows us to distinguish these effects. Incoming spillovers significantly affect the probability of cooperating with research institutes, while appropriability through the effectiveness of strategic protection matters for cooperative agreements in the vertical chain. We also find that correcting for the endogeneity of spillovers and R&D cooperation is important in order to evaluate the magnitude of the effect of spillovers on the decision to cooperate. Although not affecting the direction of the effects of incoming and outgoing spillovers on cooperation, the correction suggests that the average cooperating firm weakly increases the importance of incoming spillovers. Our results therefore provide some support for information sharing, especially within cooperative R&D agreements with research institutes as partners. Furthermore, we find that cooperative agreements with vertically-related firms can potentially diminish firms' ability to appropriate the results of the innovation process. Our results thus suggest that policymakers should concentrate their efforts less at the industry-level, targeting 'strategic' sectors, but rather at the firm-level by identifying and stimulating spillover generating firms, improving the absorptive capacity of individual firms as well as encouraging spillover enhancing cooperative agreements.

Introduction

Successful innovation depends on the development and integration of new knowledge in the innovation process. Part of this knowledge will reach the firm from external sources. Several authors have documented the existence of these external information flows and have commented on their importance for decisions at the firm level (Jaffe, 1986; Bernstein and Nadiri, 1988, 1989) and ultimately for economic growth (Romer, 1986, 1990; Krugman, 1991; Grossman and Helpman, 1991; Griliches, 1992). One challenge facing this literature has been the measurement of these information flows or “spillovers” between firms and gauging their effect on different innovation management decisions by the firm. The contribution of this paper is twofold. First, we attempt to clarify the concept of spillovers and their measurement. The second contribution of this paper is that we use measures of spillovers to analyze the decision of firms to engage in cooperative agreements in R&D.

In order to clarify the concept of spillovers, one needs to distinguish between different measures of these *spillovers*. On the one hand, there are measures of the importance of external information flows for the rate of success of the firm’s innovation process. These information sources are typically situated in the public domain and their usefulness to the firm depends on the firm’s ability to generate *incoming spillovers* from this general pool of knowledge. Many things can be measured here: the total pool of external knowledge that is potentially available, the fraction of this pool that is accessible and relevant to the firm, the know-how that is effectively absorbed and used within the firm, or the effectiveness of this absorbed knowledge for the firm’s innovative performance. On the other hand, firms attempt to appropriate the benefits of their innovations by controlling the information flows out of the company into the pool of publicly available information. The success of a firm’s innovation strategy not only depends on the success of its innovation process, but is also a function of how proficient the firm is at appropriating any benefits from its successful innovation process. Typically, the protected information is commercially sensitive and the success or profitability of a firm’s innovation strategy crucially depends on legal and strategic measures of protection

to restrict these *outgoing spillovers*. Here as well different measures are possible: the usefulness and/or degree of difficulty to a firm of protecting its own knowledge, the fraction of know-how it can keep proprietary, the potential economic returns to a given firm's own knowledge that it manages to appropriate, or the potential social returns from the non-appropriated knowledge.

Throughout the paper, we will disentangle incoming spillovers, which affect the rate of innovation of the firm, and outgoing spillovers which affect the ability of the firm to appropriate the returns from innovation. We will explore a direct measure of *incoming spillovers*, as measured by the importance of publicly available information for the innovation process of the firm, obtained from survey data on Belgian manufacturing firms. Alternative measures of incoming spillovers require the construction of a pool of available and relevant knowledge (o.a. Jaffe (1986)). The estimated effect of this pool of available knowledge on the firm's decision variables is then the spillover effect. The advantage of our measure is that it avoids the construction of a pool of available knowledge by jointly measuring the extent of the pool of relevant knowledge and its productivity for the firm's innovation process.

Using the same survey data, we can also construct a direct measure of *appropriability* which rates the effectiveness of different mechanisms for protecting the innovations of the firm. Alternatively, one could use regression analysis to calculate the average gap between private and social rates of return (Bernstein and Nadiri, 1989). But as mentioned before, this requires the construction of a pool of general knowledge relevant to the firm. The advantage of our measure of appropriability is that it is direct and firm-specific. The disadvantage of both our measures of incoming spillovers and appropriability is that their construction relies on qualitative firm-level data, which requires the necessary correction and caution in interpretation.

The second contribution of this paper is that we use these measures of incoming spillovers and appropriation to analyze their impact on the decision of firms to engage in cooperative R&D. The pervasiveness of cooperative agreements in R&D has become a significant feature in current innovation management practice. It offers firms more efficient

access to new external information and allows them to integrate this information more effectively into their innovation process. However, cooperation in R&D carries more risks with respect to the loss of commercially sensitive information and hence might diminish the firm's ability to appropriate the benefits of successful innovations. To the best of our knowledge, this is the first study that empirically investigates the relation between cooperation in R&D and spillovers. This is surprising given the extensive theoretical literature which focuses on this relationship.

We find that there is indeed a significant correlation between external information flows and the decision to cooperate in R&D. Firms that depend more on generally available external information sources as inputs to their innovation process—the *incoming spillovers*—are more likely to be actively engaged in cooperative R&D agreements. At the same time, firms that are more effective in appropriating the results from their innovation process, are also more likely to cooperate in R&D. The importance of distinguishing between measures of incoming spillovers and appropriability becomes even more apparent when analyzing the type of partner with whom firms cooperate. Higher incoming spillovers positively affect the probability of cooperating with research institutes such as universities and public or private research labs. Firms who find the publicly available pool of knowledge more important for their innovation process, are more likely to benefit from cooperative agreements with other research institutes. Better appropriability of results of the innovation process, however, increases the probability of cooperating with customers or suppliers. Commercially sensitive information, which is the result of these more applied research projects, often leaks out to competitors through common suppliers or customers. Hence, only firms that can sufficiently protect their proprietary information, are willing to engage in this type of cooperative agreements.

Furthermore, we find evidence for a reverse effect of cooperation in R&D on incoming spillovers and appropriability. Firms that cooperate in R&D find that incoming spillovers are more important for their innovation process. Cooperative agreements between research partners increases the usefulness of the publicly available pool of knowledge for the

firm's innovation process. Cooperative agreements with suppliers or customers however, reduce the effectiveness of strategic protection measures. This suggests that the commercially sensitive information that firms might disseminate indirectly through cooperative agreements with suppliers and customers, could be detrimental to the efforts of the firm to appropriate the returns from its innovation process. Hence, firms should take care to protect their proprietary information before engaging in these types of agreements. Our results therefore strongly suggest that the level of knowledge in- and outflows is not, as assumed in much of the theoretical literature, exogenous to the firm. But through their innovation activities, firms also affect their incoming spillovers and appropriation capabilities.

In the next section we discuss the theoretical issues related to external information flows and cooperation in R&D, we describe the data and set up an empirical model to analyze the relationship between the decision to cooperate and spillovers. Section 3 presents the results of our analysis and section 4 concludes.

R&D Cooperation and Spillovers

Issues

The relationship between different knowledge flows—spillovers—and cooperation is complex. The theoretical literature has mainly focused on the effect of imperfect appropriability of results from the innovation process on the incentives to innovate, when the firm cooperates in R&D. On the one hand, imperfect appropriability increases the benefits from cooperative R&D agreements. Firms that cooperate in R&D choose their R&D investments to jointly maximize profits. Hence, cooperation in R&D internalizes the positive externality created by involuntary knowledge transfers and investment in R&D is increasing in the level of the spillover. When spillovers are high enough, i.e. above a critical level, cooperating firms will spend more on R&D and are increasingly profitable compared to non-cooperating firms (d'Aspremont and Jacquemin, 1988; Kamien, Muller and Zang, 1992). On the other hand, imperfect appropriability increases the incentive of firms to free ride on each

other's R&D investments. First, partners may conceal their technological expertise while trying to absorb as much of the partner's knowledge as possible (e.g. Shapiro and Willig, 1990; Baumol, 1993; Kesteloot and Veugelers, 1994). Higher spillover levels increase partner's potential benefits from cheating. The second free riding problem results from firms that remain outside the cooperative agreement. Lower appropriability of results encourages free-riding on the R&D efforts of the research joint venture by an outsider to the cooperative agreement (Greenlee and Cassiman, 1999; De Bondt and Wu, 1997). Hence, cooperative ventures become more profitable and easier to sustain the better firms are at appropriating the benefits of their innovation process.

Imperfect appropriability of innovation results leads to information flows that increase the stock of publicly available knowledge from which other firms draw information for their own innovation process. Firms attempt to manage these incoming information flows. First, they try to increase the extent of incoming spillovers by investing in "absorptive capacity". Cohen and Levintahl (1989) argue that external knowledge is more effective for the innovation process when the firm engages in own R&D. The direct effect of higher absorptive capacity is thus to increase the effectiveness of incoming information. Secondly, a firm might increase its incoming spillovers by voluntarily trading knowledge with partners, as in the research joint venture information sharing scenario of Kamien et al (1992). Increasing the incoming spillovers between research partners is found to increase not only the profitability, but also the stability of cooperation in R&D, since it makes the potential threat of non-sharing harsher (Kesteloot and Veugelers, 1994; Eaton & Eswaran, 1997).

Finally, the choice of research approach by the firm influences the appropriability conditions it faces and the extent of incoming spillovers it enjoys. Kamien and Zang (1998) show that firms that cooperatively choose their R&D expenditures, maximize information flows—their *incoming* spillovers—through the choice of very broad research directions for the research joint venture. If the firms cannot coordinate their R&D expenditures, they are more concerned about managing their *outgoing* spillovers by choosing a more narrow

research approach which improves appropriability but at the same time limits the usefulness of external information sources for its own innovation process.

In most theoretical models on cooperation in R&D and spillovers, firms generate and receive spillovers to the same extent. Assuming symmetric incoming and outgoing spillovers makes it difficult to model the idea that firms manage these information flows. The aim of managing the external information flows is to maximize the incoming spillovers *from* partners and non-partners, while at the same time minimizing spillovers *to* non-partners and non-loyal partners. In our empirical analysis we will not be concerned with the equilibrium analysis as performed in most of the theoretical work. In the relationship between spillovers and cooperation, we want to highlight the distinction between two measures of knowledge flows, namely incoming spillovers, measured as the usefulness of external information as an input for the innovation process, and, appropriability, measured as the effectiveness in capturing value from a successful innovation. We allow for heterogeneity among firms along these dimensions. The ability to create incoming spillovers from the general pool of knowledge can be a function of other innovation activities of the firm such as own R&D, participation in cooperative agreements, the type of research the firm engages in, or the technological opportunities in the industry. At the same time, firms that cooperate pay special attention to protecting their proprietary knowledge. The ability to protect valuable information from reaching other firms also depends on the firm's innovation activities such as own R&D, on the competitive environment of the firm and the appropriability conditions in the industry. But a firm's effectiveness in protecting commercially sensitive information might be reduced by the knowledge flows created through participating in cooperative R&D agreements.

Data

The data used for this study are drawn from the Community Innovation Survey (CIS) conducted in several member states of the European Union in 1993. The survey intended to develop insights into the problems of technological innovation in the manufacturing industry

and was the first of its kind organized in many of the participating countries.¹ We will restrict attention to the subsample of innovating firms from the Belgian manufacturing industry.² These firms are distinguished from those who do not innovate based on their answers to the questions about whether they innovated between 1990 and 1992. Innovation is defined by introducing new or improved products, or, new or improved processes, and, at the same time, firms needed to have specified a positive amount spent on innovation. In the sample 60% (439) of the firms claim to innovate, while only 40% do not. This number is in line with the survey results from other EU countries (Eurostat, Statistics in Focus, 1996-2).³ Due to missing values we are left with 411 observations on actively innovating firms.

Incoming spillovers: In the questionnaire, firms rated the importance for their innovation process of publicly available information from three sources on a 5-point Likert scale (from unimportant (1) to crucial (5)). These information sources were: patent information; specialist conferences, journals and gatherings; expositions or trade fairs. We aggregated these answers by summing the scores on each of these three questions and re-scaled the total score to a number between 0 and 1 to generate a firm-specific measure of incoming spillovers: *INSPILL*.⁴ To capture the exogenous nature of spillovers, determined by technology or market characteristics, we also construct the average industry score for

¹ A more detailed analysis of this data is reported in Veugelers and Cassiman (1999).

² The authors are grateful to DWTC and IWT for providing the data. These organizations were responsible for the collection of the Belgian subsample of the CIS, which was conducted by Eurostat. A representative sample of 1335 Belgian manufacturing firms was selected and a 13-page questionnaire sent out to them. The response rate was higher than 50% (748). The researchers in charge of collecting the data for the CIS also performed a limited non-response analysis and concluded that no systematic biases could be detected (Debackere and Fleurent, 1995).

³ Only the innovating firms needed to fill out all questions in the survey. Restricting the sample to innovating firms might lead to sample selection if we believed that cooperation is an important way to innovate for firms that would otherwise not be innovative active. This is unlikely, however, given that all firms that cooperate do have some other innovation strategies, such as own R&D or some form of external knowledge acquisition (see Veugelers and Cassiman (1999)).

⁴ See Table in the Appendix for the definition of all variables used. The rescaling of a variable with a Likert scores between 1 and 5 to a variable between 0 and 1 is done for each Likert score used in the analysis: rescaled score = (score - 1)/4. This allows the comparisons of coefficients. The questionnaire did not provide a weight of the relative importance for each of the questions.

INSPILL: indINSPILL.⁵ The questionnaire thus provides a direct measure of the importance of incoming spillovers for the innovation process. Studies relying on the indirect measurement of incoming spillovers require the construction of a pool of available and relevant knowledge for each firm in the sample. In order to assess which agents benefit more from a given knowledge stock, a measure of “distance” between technology receiver and generator is included. Several approaches are used in the literature: input-output flows (Terleckyj, 1974), technology flows obtained from patent information,⁶ import or FDI flows for international channels (Coe and Helpman, 1988). Our measure avoids this problem by jointly measuring the extent of the pool of relevant knowledge and its productivity for the firm’s innovation process.

Appropriability: Firms rated the effectiveness of five different methods for protecting products and processes respectively (10 different questions overall) on a 5-point Likert scale (from 1 (unimportant) to 5 (crucial)). The five methods were: patents; brand names and copyright; secrecy; complexity; and lead time. We distinguish between two types of protection: *legal* protection of products and processes through patents, brand names or copy right, and *strategic* protection of products and processes through secrecy, complexity or lead time. Again we aggregated answers on each of these questions by summing the scores on each of these questions and rescaled the total score to a number between 0 and 1 to generate a measure of legal and strategic protection. However, we will only use strategic protection, *PROTstrat*, as a firm level variable. Legal protection never showed up as significant on the firm level, suggesting this is an industry, rather than a firm-specific characteristic. The industry averages *indPROTleg* and *indPROTstrat* capture the technology and market characteristics that determine the appropriability regime of the industry. Hence, from the

⁵ The industry is defined at the NACE 2 digit sector level and the average is the average score from the firms responding in the sample.

⁶ Various approaches have been pursued here: patent information on principal users in the Yale studies, supplementary technology codes in EPO (Verspagen, 1995), clustering techniques (Jaffe, 1986), citations (Jaffe, Henderson and Trajtenberg, 1993).

questionnaire we derive a direct measure of the beliefs of the firm's management about the effectiveness of various mechanisms to protect their innovations.

There exist two alternative ways of estimating the gap between private and social rates of return of innovation. Both have their own limitations (see Griliches, 1992). First, one can restrict attention to a specific innovation. This requires assuming that the benefits of this innovation are localized in a particular industry or range of products. Furthermore, intimate knowledge of the innovation is necessary to track information flows. The limitation of this type of study is that it is not representative and only considers "important" innovations. Second, the results of regression based studies can be used to calculate the average gap between private and social rates of return for an industry (Bernstein and Nadiri, 1989). But as discussed before, this requires the construction of a pool of general knowledge which is relevant to the firm. The advantage of our measure of appropriability is that it is firm-specific and does not require detailed knowledge of the different innovations of the firm.

Although the use of survey data yields direct firm-specific measures for incoming spillovers and appropriability, it also introduces some subjectivity into the measurement of these firm-specific measures *INSPILL* and *PROTstrat*, which would lead to problems of measurement error. A first potential problem of measurement error is the aggregation of scores of different questions. However, the different questions on the importance of information sources for the innovation process and on the effectiveness of measures of protection were grouped in the same subsection of the questionnaire. Comparing the scores on the different questions should therefore have come naturally to the respondents. Nevertheless, we experimented with different measures and combinations of these variables and all lead to similar results. Second, individual respondents may also differ in their use of the 5-point scale. This would introduce a more serious problem of measurement error.⁷ Other studies, most notably Cohen and Levinthal (1989) and Levin (1988), have found that including industry means for the qualitative variables reduces the problems of using subjective

⁷ Unfortunately, our data set lacks a panel structure that would allow for simple fixed firm effect corrections.

measures. They use the data of the Yale Survey to construct measures of appropriability at the industry level and these variables have been widely used in related applications.⁸ However, the beliefs of management about the external environment are what drive a firm's decision about whether or not to engage in a cooperative agreement. As our results indeed show, firm-specific measures better capture these effects, since they increase the explanatory power of the empirical model considerably. Our data allow for alternative corrections for measurement error, avoiding industry aggregation. We indirectly attempt to control for measurement error problems by regressing *INSPILL* and *PROTstrat* on exogenous instruments with uncorrelated measurement errors available in the data set (see below).

Closer examination of our knowledge flow variables, *INSPILL* on the one hand and *PROTstrat* on the other, shows that they do capture different effects. First, the variables are not perfectly correlated. Correlation between *INSPILL* and *PROTstrat* is 0.21.⁹ Second, we find a lot of variation in the ranking of the industries according to each of our measures. As could be expected, the chemical industry ranks high on the importance of incoming spillovers (ranked 2nd out of 19 industries) as well as on the effectiveness of patent protection (ranked 1st), but it is only ranked 8th in strategic protection. The apparel and textile industries score low on all measures. However, there are industries that score high on the importance of incoming spillovers, but low on appropriability such as the electronics industry which is ranked 4th on the importance of incoming spillovers, but only 13th for legal protection and 16th for strategic protection. As for the data of Levin et. al. (1987), we find that within industry variation in the variables is much more important than between industry variation

⁸ See among others: Levin, Cohen and Mowery (1985), Cohen, Levin and Mowery (1987), Levin (1988), Levin and Reiss (1988), Cohen and Levinthal (1989), Klevorick, Levin, Nelson and Winter (1995).

⁹ In addition, we performed a principal component analysis on the answers of the thirteen questions used for the construction of *INSPILL*, *PROTleg* and *PROTstrat*. Three principal components explain 60% of the variance and each question loaded most weight on one of the three principal components in line with our constructed measures. Not surprisingly, then, the principal components are strongly correlated with the constructed spillover and appropriability measures. The correlation between our constructed variables and the respective principal components was more than 0.92. We have performed the same analysis using the principal components. The qualitative results do not change, but interpretation is enhanced when using our constructed variables.

(see Cockburn and Griliches (1988)). This should not surprise us given the recent observation of substantial within industry heterogeneity of firm characteristics (Haltiwanger et al, 1999).

The cooperation variable: In the questionnaire the firms were asked to reveal whether they had cooperative agreements in R&D and to indicate the type of partners they cooperated with (competitors, supplier, customers, universities, other public or private research organizations). Cooperation was understood to imply an active participation of the partners in a joint R&D project. We set the variable *COOP* equal to 1 when firms indicated that they had at least one cooperative agreement with any type of partner and 0 otherwise. In the data set there are 185 firms that have at least one type of cooperative agreement in R&D. The data also allow us to distinguish different types of cooperative partners: competitors (33), vertically related firms, i.e. suppliers or customers (135) and universities or other research institutes (135).¹⁰ Therefore, in addition to pooling the data on cooperative agreements, in order to uncover common characteristics of the cooperation decision, we will also perform our analysis for cooperative agreements with vertical partners and research institutes separately.¹¹ However, it is already interesting to note that most of the cooperative agreements are vertical or with research institutes (see Robertson and Gatignon (1998) for similar results). This contrasts with the bulk of the theoretical literature, which mainly analyzes cooperative agreements between competitors.

In Figures 1 and 2 we plot the cumulative distributions of the importance of incoming spillovers for the firm's innovation process (*INSPILL*) and the effectiveness of strategic protection (*PROTstrat*) for cooperating and non-cooperating firms. These figures provide some first indication of the correlation between higher incoming spillovers and more effective

¹⁰ The questionnaire only contains information on whether firms cooperate or not, but not on budgets spent. Several firms do have cooperative agreements with different types of partners. But within one partner category, we have no information on the number of cooperative agreements. Information on the partner is also not available. Therefore, the data do not allow us to identify spillover flows to and from partners versus non-partners in cooperation.

protection, and the propensity of firms to cooperate. The cumulative distribution of cooperating firms always lies below the cumulative distribution of the non-cooperating firms, indicating a higher rating of cooperating firms of the importance of incoming spillovers as well as a higher rating on the effectiveness of protection of know-how.¹²

Model

In contrast to the large number of theory papers on the relation between spillovers and R&D cooperation, no thorough empirical analysis has been conducted on the subject, although a few papers have touched upon it. Brandstetter and Sakakibara (1998) find that R&D cooperation positively affects the research productivity of the partners and attribute this to the increased incoming spillovers between partners.¹³ Related, Henderson and Cockburn (1996) show that knowledge flows between research groups in related therapeutical classes, are an important determinant of research productivity in the pharmaceutical industry. These spillovers, measured as patent citations, thus impact the pharmaceutical firms' innovation process and determine the boundaries of their organization.

Because of methodological problems in assessing the profitability of cooperative agreements in R&D, most studies of the determinants of R&D cooperation use the frequency of occurrence of R&D cooperation to assess which characteristics are more likely to lead to R&D cooperation (Röller et al, 1997; Kleinknecht and Van Reijnen, 1992; Colombo and Gerrone, 1996).¹⁴ These studies provide strong evidence that the size and R&D orientation of firms affect R&D cooperation. This is reminiscent of the absorptive capacity idea which stresses the need to have in-house (technological) power to optimally benefit from R&D

¹¹ The limited number of cooperative agreements between competitors does not allow us to do a similar analysis with this latter group.

¹² For eight out of the nine questions used for the construction of the spillover and protection variables, the mean answer for cooperating firms was significantly higher, at the 1% level of significance, than the mean answer for firms that did not cooperate. For the importance of trade shows and seminars the mean answers were not significantly different, although the cooperating firms had a higher mean score.

¹³ See also Kleinknecht (1999) for a related result.

¹⁴ The discussion focuses around the use of subjective (e.g. through questionnaires) versus objective measures of performance (such as financial measures or stock market responses). Unfortunately,

cooperation. We allow for a non-linear effect of size on the probability of cooperation in R&D (*SIZE*, *SIZEsq*) and include a dummy variable for whether or not the firm performs R&D on a permanent basis (*PermRD*). By including *INSPILL* in the relation, we can test whether the effect of absorptive capacity on R&D cooperation, in addition, runs through its effect on the importance of external information sources. At the same time, internal R&D capacity is an intrinsic element of any strategy to protect know-how. This adds another indirect effect of R&D capacity on R&D cooperation, included through *PROTstrat*.

As work by Mariti and Smiley (1983) and Tyler and Steensma (1995) has indicated, other motives such as cost and risk sharing as well as getting access to new technologies are important incentives for cooperation. Sakakibara (1997a,b) finds that access to complementary knowledge is one of the most important objectives for establishing government sponsored research corporations in Japan. Our survey information allows us to proxy for these motives. The firms rated the importance of different obstacles to innovation on a scale of 1 (unimportant) to 5 (crucial). When costs are an important obstacle to innovation, we expect to observe more cooperative agreements with the purpose of cost sharing. We construct an aggregate measure of the responses to four questions on the importance of costs as an obstacle to innovation (*COST*). These obstacles were: a lack of suitable financing; high costs of innovation; a long pay-back period; and, difficult to control costs of innovation. Similarly, we expect that higher risks and uncertainty in the innovation process favor risk sharing through the organization of cooperative agreements in R&D. *RISK* measures the importance of high risks as a barrier to innovation. Finding suitable partners to cooperate with requires knowledge about technological opportunities in the market. *TECH* measures the availability of technological information for innovation within the firm. Although a lack of internal technological know-how may drive firms to cooperate in order to access missing technologies externally, it simultaneously reduces the scope for complementarities that could be exploited through cooperation. Hence, we use *TECH* as a

financial measures about the performance of cooperative agreements in R&D are typically not reported

measure of the potential for realizing complementarities with partners in a cooperative agreement in R&D.¹⁵

The focus of the analysis is on the effects on R&D cooperation of our measures of incoming spillovers and appropriability. These variables are included both at the firm and the industry level. We expect that higher incoming spillovers increase the scope for learning within cooperative R&D agreements and beyond. Because of an improved technological competence of the partners, the marginal benefit of forming a research joint venture is higher, implying a higher probability of cooperation. The theoretical literature does not provide clear-cut predictions about the signs of the appropriability variables. On the one hand, lower appropriability or higher incoming spillovers, increases the scope for the internalization of information flows through cooperation in R&D. But, on the other hand, lower appropriability increases free rider problems related to R&D investments, which reduce profitability and threaten the stability of cooperative agreements in R&D. When the appropriation regime is tight, i.e. protection is more effective, firms can more easily enter into R&D cooperation, controlling knowledge flows to non-partners or non-loyal partners.

The level of incoming spillovers and the effectiveness of appropriation mechanisms might not only affect profitability and hence the decision to cooperate, but, when firms use cooperative agreements as a vehicle to manage external knowledge flows, the decision to cooperate could also influence the actual level of incoming spillovers and the effectiveness of appropriation strategies. Cooperating firms may try to maximize *incoming* spillovers among partners through information sharing, which will enhance the profitability as well as the stability of cooperation. Moreover, in response to free-riding, firms will want to limit

as a separate entry in the financial accounts of the firm.

¹⁵ See Data Appendix for a precise definition of all the variables. Note that our sample consists of innovating firms. Hence, we expect these variables to affect how they organize their innovation process, rather than whether they innovate or not. The construction of the variables *COST*, *RISK* and *TECH* might again introduce some measurement error/subjectivity because of the use of a subjective rating scale. However, we will assume that this measurement error is uncorrelated to the measurement error/subjectivity from their response to the importance of external sources of information and the effectiveness of measures of protection. This is consistent with the low correlation between *INSPILL* and *PROTstrat* on the one hand and *COST*, *RISK* and *TECH* on the other. Dummy variables for the industry, when included, were not significant and did not affect the results.

outgoing spillovers to non-partners. Although outgoing technology flows to partners are essential in information sharing agreements in search of synergies, such agreements could possibly reduce the effectiveness of measures of protection. Firms need to carefully manage this exposure of own know-how within the alliance in view of the threat of opportunistic partners. We expect that firms that are considering R&D cooperation have an incentive to invest in mechanisms increasing appropriability in general and becoming more successful at controlling information sharing with their partners, as well as limiting free-riding by non-partners. To address this possible endogeneity problem between cooperation and information flows, we will model a system of simultaneous equations of *COOP*, *INSPILL* and *PROTstrat*. Furthermore, the estimation of this system of equations might alleviate problems of measurement error arising from the use of qualitative measures of incoming spillovers and strategic protection by regressing *INSPILL* and *PROTstrat* on exogenous instruments.

Setting up a system of simultaneous equations of *COOP*, *INSPILL* and *PROTstrat*, requires specifying exogenous variables for *INSPILL* and *PROTstrat*. For incoming spillovers, *INSPILL*, the literature seems to suggest that absorptive capacity through internal technological capabilities is important to optimally benefit from external information flows. Therefore, firms that perform R&D on a permanent basis should attribute higher importance to incoming spillovers. Given that generic research is more difficult to appropriate, firms that find sources of basic R&D more important for their innovation process, relative to information sources of applied R&D, are more likely to benefit from incoming spillovers and hence are expected to have a higher score on *INSPILL* (Vonortas, 1994; Kamien and Zang, 1998). The variable *BasicRD* measures the importance for the innovation process of information from research institutes and universities relative to the importance of suppliers and customers as an information source. We use this variable to proxy for the “basicness” of

R&D performed by the firm.¹⁶ The industry variable *indINSPILL* is included as well to capture the technological conditions of the industry influencing knowledge flows.

The strategic protection variable *PROTstrat* will be influenced specifically by variables characterizing the competitive environment of the firm. The more competitive the environment, the more a firm is expected to invest in protecting any technological competence. More export intensive firms typically face a more competitive environment (*EXPint*). Firms with a higher internal technological capacity might not only be better at absorbing incoming spillovers, but also be better at protecting their knowledge through secrecy, complexity or lead time. Therefore, we include *PermRD* as an explanatory variable. The variable *indPROTstrat* is included to capture technological conditions shaping strategic protection possibilities in the industry.

Table 1 presents some descriptive statistics about the variables used. Consistent with our model hypotheses, the mean values of all variables are higher for cooperating firms than for firms that have no cooperative R&D agreements. We estimate a Probit model of whether the firms decide to cooperate or not.¹⁷ The estimation is corrected for endogeneity of *INSPILL* and *PROTstrat* by estimating the equations by a 2SLS procedure. We should also note that this correction simultaneously allows us to address the potential measurement error problem for the *INSPILL* and *PROTstrat* variables.

Results

First, we discuss the importance of incoming spillovers and appropriability for the cooperation decision of the firms, with and without correcting for endogeneity of the knowledge flow variables. Next, we estimate the models for vertical cooperation and cooperation with research institutes separately. Finally, we discuss what determines the level of incoming spillovers and appropriability using the results of the 2SLS estimation.

¹⁶ The questionnaire grouped all the questions on the importance of different information sources for the innovation process in the same subsection. Scores of the same firms should be readily comparable.

Results on cooperation

The coefficients in Table 2 present the marginal effect of the independent variables on the probability of cooperating, while keeping everything else constant. Regression (1) only includes incoming spillovers and appropriability measures at the industry level. At this level, only legal protection significantly affects cooperation. A 1% increase in the measure of legal protection at the industry level, increases the probability of cooperation by 4%. Adding firm-specific measures of incoming spillovers and strategic protection significantly increases the explanatory power of the regression (see regression (2)). *Incoming* spillovers have a positive and significant effect on the probability of firms cooperating (*INSPILL*). The existing base of know-how is better tapped by cooperating firms because of the improved technological competence of the partners. This increases the expected profitability of cooperative agreements and hence makes them more likely to occur.

Similarly, higher appropriability through strategic protection has a positive effect on the probability of firms cooperating. The more effective is strategic protection, the better firms control the outflow of commercially sensitive information, and the more likely they are to engage in cooperative agreements (*PROTstrat*). Hence, better appropriability reduces the potential for free riding within and beyond the cooperative agreement and improves the stability of these agreements. However, while the effect of incoming spillovers on cooperation is significantly positive, regressions (2) and (3) show that the effect of appropriability through strategic protection is moderated by the R&D orientation of the firm. Once corrected for permanent R&D, the coefficient of *PROTstrat* remains positive, but loses significance. This result suggests that the R&D capabilities of the firm not only play an important role in successfully innovating, but also in increasing the effectiveness of appropriating returns from its innovation process.

Note that by using this ratio of two scores, the potential problems of the subjectivity of these measures is reduced.

¹⁷ Logit estimations give similar results.

As regressions (4) and (5) demonstrate, the correction for the endogeneity does not change our findings on the signs and significance of the coefficients of the spillover effects, but significantly increases the estimated coefficients.¹⁸ The increase in the estimated coefficients might not only indicate an endogeneity problem, but could also reflect a problem of measurement error with *INSPILL* and *PROTstrat*. In which case the uncorrected estimates are biased towards zero.¹⁹

Next, we discuss the non-spillover determinants of cooperation. The signs and significance levels of all the coefficients of these variables remain fairly robust across the different regressions. Not surprisingly, larger firms are more likely to cooperate. The effect of firm size is very significant, with evidence for a non-linear relation. When costs are an important obstacle to innovation, innovating firms have a higher probability of engaging in cooperative agreements (*COST*). While cost-sharing seems to be an important driver for cooperation, risk-sharing is not. On the contrary, firms for which risk is an important barrier to innovate are less likely to cooperate (*RISK*). Viewed from a transaction cost perspective, however, this result is not so surprising. Minimizing opportunistic partner behavior in cooperative contracts will be more difficult when the technology is characterized by a large amount of uncertainty. It seems important to distinguish between costs and risks when analyzing the cooperation decision. With an explanatory variable that combines cost and risk factors, insignificant results are obtained. As expected, the higher the availability of

¹⁸ IndPROTstrat becomes significant in regressions (5) and (6), while indINSPILL becomes significant in regression (7). These variables are good instruments for INSPILL and PROTstrat (see below). Hence, we interpret the negative signs for these industry variables in the 2SLS equations as corrections. Incoming spillovers and appropriability have important explanatory power as deviations from the industry mean.

¹⁹ In order to consider the regression of the endogenous variables on all exogenous variables as a correction for measurement error, we need to assume that the measurement error of the other qualitative variables (*COST*, *RISK* and *TECH*) is uncorrelated with the error in *INSPILL* and *PROTstrat* (see footnote 15). Nevertheless, estimating the model without these other qualitative variables did not change our results on the coefficients of *INSPILL* and *PROTstrat* significantly. Furthermore, we could not reject the null hypothesis for no endogeneity of a Hausman test for this case.

technological know-how for innovation, which increases the scope for complementarities to exploit through cooperation, the higher is the probability of cooperation (*TECH*).²⁰

The overall predictive power of the estimated cooperation model is good; for instance, for the exogenous model of regression (2), more than 71% of all cases are predicted correctly.²¹ There is however a tendency to underpredict the number of cooperative cases: only 66% of all cooperations were predicted correctly.²²

Spillovers and Cooperation with different types of partners

The importance of distinguishing between incoming spillovers and appropriability is highlighted when we distinguish between cooperation along the vertical chain, i.e. with suppliers or customers, and cooperation with research institutes. In our data set, 33% of the firms cooperate with customers or suppliers, while 33% cooperate with research institutes. Of the cooperating firms, 46% have cooperative agreements of both types. Regressions (6) and (7) of Table 2 present the results of the separately estimated probit models, corrected for endogeneity through a 2SLS estimation.

While the effectiveness of legal protection at the industry level positively affects both types of cooperative agreements, some interesting differences emerge between research and vertical cooperation with respect to incoming spillovers and strategic protection. Incoming spillovers have a significantly positive effect on cooperation with research institutes. Firms cooperating with research institutes seem to attach more importance to incoming spillovers, while incoming spillovers do not seem to affect the likelihood of vertical cooperation. A different pattern emerges for appropriability through strategic protection. The effectiveness of strategic protection is not important when deciding about cooperating with research institutes.

²⁰ Sakakibara (1997a,b) also finds that expected complementarities are one of the most important motives for forming government sponsored research consortia in Japan. Where Sakakibara (1997a, b) explicitly analyzed the motives for cooperation in R&D, the CIS questionnaire analyzed innovative behavior in general. The questions from which we derive our explanatory variables were never directly related to the decision of the firm to cooperate, but were rather related to the firm's innovative behavior. As a result, we expect our results to be less driven by what managers answering the questionnaire thought was the "correct" answer with respect to the cooperation decision.

²¹ The naïve model would classify 55% correctly.

²² The percentages for regression (4) are comparable: 72% and 69% respectively.

For vertical cooperation, however, the effectiveness of strategic protection is important to induce cooperation. Note that in this case strategic protection remains significant, even after controlling for permanent R&D activities by the firm. All this seems to suggest that outgoing spillovers between industrial partners are more critical than spillovers to non-industrial partners. This is reminiscent of the idea that competitors learn about their rivals through common suppliers or customers. Furthermore, firms want to avoid backward integration by customers or forward integration by suppliers because of what they learn through cooperative agreements. These results also indicate that our measure of incoming spillovers proxies for more generic information, which is generated and disseminated through R&D cooperation with research organizations but which is not as commercially sensitive as the more practical information that is generated and disseminated in cooperative agreements along the vertical chain.

For both types of cooperative agreements, firm size is an important determinant. But our results also show that the other explanatory variables of the cooperation decision for the pooled case nicely fall into two categories: variables affecting cooperation along the vertical chain on the one hand and variables affecting cooperation with research institutes on the other. Permanent R&D activities (*PermRD*) only directly affect the decision to cooperate with research institutes. It is also interesting to observe that high costs (*COST*) and high risks (*RISK*) are only relevant for cooperation with research institutes. These results are related to the more basic nature of joint R&D with research institutes. Absorptive capacity, built through continuous R&D investments, is necessary to appropriate any benefits from these R&D agreements. In addition, this type of agreements entails higher costs and thus scope for cost sharing and higher risks with an increasing probability for opportunism by partners. The search for external know-how and complementarities (*TECH*), however, is important for vertical cooperative agreements, where the matching of existing technological capabilities is an important element of the cooperative agreement.

Incoming Spillovers and Strategic Protection

In Table 3 we present the results of the second-stage regressions of *INSPILL* and *PROTstrat* respectively. Regressions (1) and (2) use the predicted value for cooperative agreements of the pooled regression and thus correspond to regression (4) in Table 2. Regressions (4) and (5) distinguish the type of cooperative agreement for the predicted value of the cooperative agreement, corresponding to regressions (6) and (7) in Table 2. The results of Table 3 suggest that there is only weak evidence for endogeneity of *INSPILL* and *PROTstrat*, with respect to the cooperative decision.²³ On the one hand, firms that cooperate will have a higher rating of importance of *incoming* spillovers for their innovation process. This positive coefficient, although only significant at the 10% level, is consistent with an information sharing explanation of cooperation where cooperating firms increase their *incoming* spillovers. As regression (3) shows, this effect is related to cooperative agreements involving research institutes, where there are more opportunities for information sharing due to the more basic nature of research projects. On the other hand, regression (4) suggests that vertical cooperative agreements would reduce the effectiveness of strategic protection. The commercially sensitive information that firms might disseminate indirectly through cooperative agreements with suppliers and customers, could be detrimental to the efforts of the firm to appropriate the returns from its innovation process. Therefore, care should be taken to protect one's proprietary information before engaging in these types of agreements. Our results demonstrate that there is an effect of cooperative agreements on both the importance of incoming spillovers and the effectiveness of protection. This implies that by engaging in different types of cooperative R&D agreements, firms can affect their knowledge in- and outflows.

Turning next to other determinants of incoming spillovers and strategic protection, we find that absorptive capacity as measured by *PermRD* positively affects the importance the firm attaches to incoming spillovers, but the effect is not significant. The R&D orientation of

the firms (*BasicRD*), however, is an important determinant of incoming spillovers. Firms involved in more basic R&D projects consider incoming spillovers more important for their innovation process. This result is reminiscent of Kamien and Zang's (1998) approach to endogeneizing spillovers through the choice of research design. Not surprisingly, firms operating in industries characterized by easier external technology appropriation are more likely to rate incoming spillovers as important (*IndINSPILL*). While permanent R&D activities did not significantly affect incoming spillovers, they do increase the effectiveness of strategic protection. This relates to the result discussed earlier, where strategic protection lost significance in explaining a firm's cooperation decision when controlling for permanent R&D activities of the firm. Furthermore, firms facing tougher competitive environments, such as exporting firms (*EXPint*) will more effectively protect their know-how strategically. Finally, technology or market characteristics favoring strategic protection will help firms to manage outgoing flows of information (*IndPROTstrat*).

Conclusions

Our results on the relationship between firm-specific spillovers and cooperation measured at the firm level seem to suggest that indeed *incoming* and *outgoing* spillovers have important and separately identifiable effects: firms with higher incoming spillovers and lower outgoing spillovers, i.e. better appropriation, have a higher probability of cooperating in R&D. Zeroing in on the type of partner in the cooperative agreements allows us to distinguish these effects. Incoming spillovers significantly affect the probability of cooperating with research institutes, while appropriability through the effectiveness of strategic protection matters for cooperative agreements in the vertical chain. This latter result does not support most of the theoretical models evaluating the relation between spillovers and R&D cooperation. These models

²³ The Hausman test for endogeneity rejects the null hypothesis for no endogeneity of INSPILL and PROTstrat at the 1% level of significance only for the case of cooperation with research institutes. For the other case, the null could not be rejected.

would predict that firms are more likely to form cooperative agreements in R&D when the appropriation regime is loose.

Correcting for the endogeneity of spillovers and R&D cooperation is important in order to evaluate the magnitude of the effect of spillovers on the decision to cooperate. Although not affecting the direction of the effects of incoming and outgoing spillovers on cooperation, the correction suggests that the average cooperating firm weakly increases the importance of incoming spillovers. Our results therefore provide some support for information sharing, especially within cooperative R&D agreements with research institutes as partners. Furthermore, we find that cooperative agreements with vertically related firms can potentially diminish firms' ability to appropriate the results of the innovation process. Our results thus suggest that policy makers should concentrate their efforts less at the industry-level, targeting "strategic" sectors, but rather at the firm-level by identifying and stimulating spillover generating firms, improving the absorptive capacity of individual firms as well as encouraging spillover enhancing cooperative agreements.

Additional empirical work is needed to verify the robustness of our results. The EUROSTAT/CIS data are a rich data set, allowing for the replication of this exercise for other European countries. However, the qualitative nature of most of the information limits the analysis in terms of quantifying R&D cooperation, R&D spillovers and their relation. Furthermore, in the absence of a panel data set it is very hard to control for unobserved firm heterogeneity. We hope that in the future alternative data sources will become available which allow for the construction of similar, more quantitative, measures of incoming spillovers and appropriability across a panel of firms. In addition, our results provide some interesting suggestions for further theoretical work on the issue of spillovers and R&D cooperation. First, the importance of the distinction between incoming spillovers and appropriability as a determinant of different types of cooperative agreements in R&D should be developed in more detail. Different spillover measures seem to have a separately identifiable impact on the firm's cooperation decisions. Second, the relation between spillovers and cooperative

agreements should be analyzed in the broader context of the firm's innovation strategy. Firms that decide to be innovation active need to understand the complementarities that exist between own R&D programs, cooperative agreements in R&D and external technology acquisition in order to take advantage of publicly available information within the innovation process and to better appropriate the results of successful outcomes of the innovation process. We still have a poor understanding of these issues and hope that our results provide some useful directions towards improving theoretical modeling of these questions.

DATA APPENDIX

The data is a cross-section of Belgian manufacturing firms in 1992. A representative sample of 1335 Belgian manufacturing firms was selected and a 13-page questionnaire sent out to them. The response rate was higher than 50% (748). The researchers in charge of collecting the data for the CIS also performed a limited non-response analysis and concluded that no systematic biases could be detected (Debackere and Fleurent, 1995). From the raw questionnaire data we constructed the variables for our analysis described in Table A1.

For example:

$$INSPILL = \frac{\text{Score Patent Info} + \text{Score Specialized Conferences} + \text{Score Trade Shows} - 3}{12}$$

The estimation procedure (2SLS) used to correct for endogeneity of *COOP* (*COOPVERT*, *COOPRES*) and *INSPILL* and *PROTstrat* is to regress the endogenous variables on all the assumed exogenous variables in the first stage. In the second stage, we use the predicted values of the endogenous variables as independent variables in the specified regressions of Tables 2 and 3.

Table A1: Description of Variables

<i>COOP</i>	<i>COOP</i> =1, if firms cooperate with 1. Suppliers, or, 2. Customers, or, 3. Competitors, or, 4. Public research institutes, or, 5. Private research institutes, or, 6. Universities.
<i>COOPVERT</i>	<i>COOPVERT</i> =1, if firms cooperate with 1. Suppliers, or, 2. Customers.
<i>COOPRES</i>	<i>COOPRES</i> =1, if firms cooperate with 1. Public research institutes, or, 2. Private research institutes, or, 3. Universities.
<i>SIZE</i>	Firm Sales in 1992 in 10 ¹⁰ BEF.
<i>SIZEsq</i>	Firm Sales in 1992 in 10 ¹⁰ BEF squared.
<i>EXPint</i>	Export share in total Firm Sales
<i>PermRD</i>	<i>PermRD</i> =1 if the firm's research and development activities have a permanent character.
<i>INSPILL</i>	Sum of scores of importance of following information sources for innovation process (number between 1 (unimportant) and 5 (crucial)): 1. Patent information 2. Specialized conferences, meetings and publications 3. Trade shows and seminars. (rescaled between 0 and 1)

<i>PROTstrat</i>	Sum of scores of effectiveness of following methods for protecting new products/ processes (number between 1 (unimportant) and 5 (crucial)): 1. Secrecy for protecting products, 2. Complexity of product or process design for protecting products, 3. Lead time on competitors for protecting products, 4. Secrecy for protecting processes, 5. complexity of product or process design for protecting processes, 6. lead time on competitors for protecting processes. (rescaled between 0 and 1)
<i>IndINSPILL</i>	Mean of <i>INSPILL</i> at industry level. Industry level is defined at 2-digit NACE.
<i>IndPROTstrat</i>	Mean of <i>PROTstrat</i> at industry level. Industry level is defined at 2-digit NACE.
<i>IndPROTleg</i>	Mean of <i>PROTleg</i> at industry level. Industry level is defined at 2-digit NACE. <i>PROTleg</i> is Sum of scores of effectiveness of following methods for protecting new products/processes (number between 1 (unimportant) and 5 (crucial)): 1. Patents for protecting products, 2. Registration of brands, copyright for protecting products, 3. Patents for protecting processes, 4. Registration of brands, copyright for protecting processes. (rescaled between 0 and 1)
<i>COST</i>	Sum of scores of importance of following obstacles to innovation process (number between 1 (unimportant) and 5 (crucial)): 1. No suitable financing available, 2. High costs of innovation, 3. Pay-back period too long, 4. Innovation cost hard to control. (rescaled between 0 and 1)
<i>RISK</i>	Importance of high risks as an obstacle to innovation (number between 1 (unimportant) and 5 (crucial), rescaled between 0 and 1).
<i>TECH</i>	$TECH = 1 - NOTECH$ <i>NOTECH</i> = Importance of lack of technological information as an obstacle to innovation (number between 1 (unimportant) and 5 (crucial), rescaled between 0 and 1).
<i>BasicRD</i>	Ratio of between: 1. Sum of scores of importance of following information sources for innovation process (number between 1 (unimportant) and 5 (crucial)): a. Universities, b. Public research institutes, and c. Technical research institutes 2. Sum of scores of importance of following information sources for innovation process (number between 1 (unimportant) and 5 (crucial)): a. suppliers of materials, b. suppliers of equipment, and c. customers.

Figure 1: cumulative distribution of importance of incoming spillovers for cooperating and non-cooperating firms

Figure 2: cumulative distribution of effectiveness of strategic protection for cooperating and non-cooperating firms
